How delicious the air is as we tramp upon the crisp heather! Every step seems to give us new life and strength; and we think of our former city selves with a sort of pitying contempt. We have reached the summit of a rocky knoll, and a dream of beauty lies before us. The silence in which it has spell-bound us is broken by my friend croaking out, “It's not photographic.” Quoth I, “That's true, but I am determined to have it. Let us skirt round the valley till the view composes itself photographically. I expect from yon rock peering from the birches we shall find the fitting point of view. But, friend, there are some legs much given to make a toil of a pleasure; pray remember that, like the illustrious Hamlet, I am somewhat ‘fat and scant of breath.’” And so, with light hearts and hats, we saunter on, happy as the skylark that hangs above us, turning sunshine into music. Philosophers might moralise, as the bee hums, the bird chirps, and the rabbit starts away with pointed ears and white feet, how things so insignificant in themselves can add a charm to the sunny picture; but we are content to enjoy life, pausing occasionally in our climbing to admire the view—that is, to take breath, and tell each other it is very warm.

At last we mount the desired point. “That will about do,” says my friend; to whom I reply, “Not quite; it wants a foreground; let us try that peak behind the pines.” As we mount the peak I exclaim, “Now we have it; a few yards to the right—there, it is perfect. I feel relieved, like a man who has done his duty. Let us sit down now, and have a whiff of the enp—no, of the pipe—that cheers, but not inebriates.”

Presently I rouse from a pleasant dreaminess with a voice percolating in my ear, “Now, my fat friend, why did you choose this exact spot?” Puffing out a delicate cloud of the carbonized weed, I reply, “My thin accomplice, a multitude of collateral and unexplainable influences may converge to the formation of one resolve—that is to say, I felt it to be the right spot. To be more particular, we have a foreground here. You remember how a man brought his son to Sir Joshua Reynolds for tuition, saying

\* Excess of muriatic acid will dissolve a portion of the chloride of silver, and so invalidate the accuracy of the test.—ED. PHOTO. NEWS.

\* Concluded from page 236.

that he could already paint the backgrounds; and that Sir Joshua replied, 'Then he has no need to come to me.' Now, what the background is to the portrait, the foreground is to the landscape. Speaking generally, the whole effect of the picture depends on it. If you look through our exhibitions, you will find many pictures that fail in effect for want of power in the foregrounds. When the upper and lower parts of a picture are painted with the same degree of power and technical detail, they have a weakness and flatness of effect quite contrary to the feeling of nature. Observe these pines before us. About ten o'clock the sun will flash among their bold, shadowy branches; whilst that little pool, to the left, will reflect their dark stems in its quiet gleam, composing a powerful foreground that will set off the retiring distances of the view. It is the great difficulty. The finest view without a good foreground will make a poor picture. Another thing in photography is, that the distance must have a degree of distinctness about it. As seen from the other rock we were upon, the hill that enclosed the view was so indistinct that it would have appeared in a photograph as a mere stain. Here, you see, it is different; we have some distinctness of rocky shape and shade. When I came here, some paces to the right, to escape the straight line of that tall pine, which came close upon that other straight pine in the middle distance, jarring the eye, you asked me if one should compose by rules? It is better just to move about till the eye is satisfied.

I believe that any sort of line or curves may appear in any part of a picture, on condition, look you, that it is duly balanced by the other parts, and brought into harmony with the whole. A man with well-poised body and vigorous limbs may walk with what step he pleases, and climb where he will; and he will always look graceful and noble. But a man not so fortunately constituted will find the greatest assistance in crutches; but he must not attempt the same heights as the other, or, when he thinks to be sublime, he will only be ridiculous. If he would go safely, he must go solely by the rule of crutch. That is a parable. If a man has not the feeling in him, there are general rules that will greatly assist him; such as, to repeat the main lines and curves of his picture *with a difference*—i.e., likeness in unlikeness, which is fundamental in all arts that deal with beauty or grandeur; as marked, for instance, cadences of music and rhythm; and more especially in rhyme, the whole charm of which lies in the same sound being repeated in a different form. When there must be some contrasting lines and curves, and varied gradations, and masses of light and shade, and a strong background, a figure seated on a wheelbarrow, or the like, casting a deep shadow along the ground, may do, if nothing better can be had. You ask me, How do you know when a man requires to compose by rule? There are two kinds of artists: the one is born an artist, the other is made after he is born. The one has an impassionate love of nature for her own sake; the other regards her very much as a lay figure that will help him on in his business. Listen to Wordsworth:—

"When like a rose  
I bounded o'er the mountains, by the sides  
Of the deep rivers and the lonely streams,  
Wherever nature led; for nature then  
To me was all in all. The sounding cataract  
Haunted me like a passion; the tall rock,  
The mountain, and the deep gloomy wood,  
Their colours and their forms, were then to me  
An appetite, a feeling and a love  
That had no need of a remoter charm,  
By thought supplied, nor any interest  
Unborrowed from the eye."

The man who feels like this is a born artist, upon condition that he has the faculties required for technical delineation. The made artist has merely the technical faculties, and must work according to the rules he has been taught; and, fortunately for him, there is a plentiful demand for the

sort of pictures he produces, which are apt to run into hard and exaggerated details, just because he does not feel the subtle charm of nature. So in photography. Almost every man, with observation and patient study of good pictures, may himself produce very acceptable pictures, especially if he confines himself to views of no great extent.

Raising myself from the reclining position, I exclaim, What a scene this is! The very silence is sublime! What a mighty calmness of golden glare and tremulous dazzle! How gorgeously that trunk of wood rejoices in the sunshine! And what repose comes from those birches on the opposite cliff, that droop their beauty against the bosom of the sky! And how that tender heat-haze, at the base of the hill, softens the distance, and adds a charm to the whole scene! Photography is impotent here. We require a lower light to throw out shades, and get a mellowing idea of the different distances; for it cannot be too strongly impressed that without due gradations, as well as masses of light and shade, a true idea of nature cannot be rendered on a small scale. The wide glare of view, that is so sublime in its magnitude, would look petty, and lose all character, mounted on eleven by nine inches.

And now, my friends, let us walk round that grand hill and be back for the great event which is to take place at seven o'clock. The tureen of "hotch-potch" has been emptied; the salmon has vanished; and the other things—where are they? Packed very safely away. A philosopher could not have better opportunity of reflecting on the wonderful connection of the inner and outer man, and how the mind is improved in proportion as the stomach is contented; for we are growing as wise as Burns's "two dogs," and as funny as—as everybody is in like circumstances. Our friend of "the wet" is the grand butt of the evening. It seems that when his tent was stretching its legs, one of them gave way, and the bath, plates, and developer fraternised together in a mode that left him nothing to do, poor fellow, but admire nature and feel miserable. But "nae man can tether time or tide;" and as our legs grow conscious that they also have been stretched, we call for the old lady and the candles, having agreed to meet for breakfast at six o'clock.

Accordingly, we have re-assembled at that hour to congratulate each other on—a day of pouring rain! Of course the wit of the company (and a small ingredient of that article goes a far way in such circumstances, when every one is prepared to be jolly) is levelled at me, for having let the fine day slip; and, of course, I fall back on the old tactics of carrying the war into the enemy's camp, by advising them to set to with their developing, and prophesying that half of their plates would be under-exposed, the motto now seeming to be "speed rather than excellence," and that one of them at least will prove to have been exposed to two views. Whereupon I am saluted with a regular chorus of "fox and sour grapes," with original variations. You want to know where I am going to, do you? To have a walk, to be sure, among the hills; they never look grander than in such a storm. You wish me joy? Thank you. And what of photography, do you ask? I have fixed on my view, and shall remain here till I take it in three different lights, giving to each two plates of different exposures, so that I am cock-sure of a good picture. I already feel as if I had it safe in Edinburgh, and were exhibiting it in No. 5, St. Andrew Square. Whereupon one gentleman informs me that it is a pleasant exercise to cook your hare before it is caught; and another exclaims that there are people in the world who have the art of hallooing before they are out of the wood; and I retire amidst a volley of such like entertaining and instructive remarks.

I shall reveal no more of our rural life, except that in our merry-makings we are strictly sober and orderly; for we have come not merely to take photographs, but to lay in a stock of health. In short, we have turned ourselves out to grass.

## THE PREPARATION OF DIFFRACTION GRATINGS.

BY LORD RAYLEIGH, F.R.S.\*

A PHOTOGRAPHER accustomed to either the plain albumen or the Taupenot process will find it very suitable for gratings. The hardness of the surface, which allows varnish to be dispensed with, is a great advantage. In my experiments with plain albumen, the principal difficulty was the purely photographic one of avoiding stains. It must be observed, however, that in actual use the gratings are not seen in focus, and that excellent spectra may be obtained from copies which a photographer would be inclined to throw away at once as hopelessly faint and dirty. The objection to the Taupenot process is the trouble of preparing the plates; but this is much mitigated when the plan is adopted of preparing large pieces to be afterwards cut up.

Among those requiring development, the tannin process is the one with which I have been most successful. In order to counteract the well-known tendency of the film to loosen, a preliminary coating of dilute albumen or gelatine is generally necessary. In the production of gratings the photographer must not be satisfied with merely keeping the film on the glass; the slightest tendency to looseness must be considered highly objectionable. The plates are coated with Mawson's collodion, excited in an ordinary silver bath, washed first in distilled water and afterwards under the tap, and then immersed for a minute in a well-filtered fifteen-grain solution of tannin. On removal from the tannin, they are set up cornerwise on blotting-paper to drain and dry.

For the development of these plates I prefer a solution of gallic acid employed in a dish, though I have obtained very good results by the ordinary method with pyrogallie acid. Prepare the two following:—

1. Gallic acid	...	...	100 grains
Alcohol	...	...	2½ ounces
Distilled water	...	...	2½ "
2. Nitrate of silver	...	...	100 grains
Glacial acetic acid	...	...	2 ounces
Distilled water	...	...	16 "

The dish used for developing should be of glass, and is best cleaned with a little strong nitric acid, which may be used over and over again. The developing solution is prepared by mixing 1 and 2 in equal parts, and diluting with water to half the strength. The alcohol helps to keep the film tight, and the development is well under control. In warm weather the operation may take an hour; but much depends upon the exposure, and still more upon the temperature. The proper point to which to carry the development can only be learned by experience; but the beginner is most likely to err on the side of excess, particularly if he uses pyrogallie acid. If, as is desirable, the film be creamy and thick, the spectra of a candle do not appear to advantage at this stage, in consequence of the unaltered iodide of silver. For fixing, "hypo" is the safest, though cyanide may be used if the film will bear it.

Tannin plates when finished are hardly secure without varnish; but there is considerable risk of spoiling gratings in the operation if an ordinary negative varnish be used. The crystal (benzole) varnish, which is applied cold, is much easier to use, and gives adequate protection.

But the process which I am now most inclined to recommend is that introduced by Mr. Wharton Simpson, and known as the collodio-chloride process. The collodion, which may be procured ready for use from Messrs. Mawson and Swan, of Newcastle, consists of an emulsion of finely divided chloride of silver held in suspension by the dissolved gun-cotton, together with a carefully adjusted excess of free nitrate. After a time the chloride of silver is precipitated, and the preparation becomes useless; but if properly mixed in the first

instance, it will remain fit for use for weeks, or even months. In the production of gratings the consumption is very small; so that, if required for this purpose alone, it is well to order it in small quantities.

In order to secure a proper adhesion, I have found a preliminary coating of albumen absolutely necessary. The white of an egg beaten up with a pint of distilled water gives a solution of sufficient strength. The plates, previously cleaned, are coated in any way that may be found convenient, and then set up on blotting-paper to drain and dry. The principal precautions necessary are to filter the albumen very carefully, and to work in a room free from dust. It will generally be convenient to prepare a considerable number of plates at a time. Though of almost infinitesimal thickness, the film of albumen produces a very marked effect. Without the albumen the skin of collodion will usually come right away from the glass when washed under the tap; with it the adhesion is remarkably good, and the film so tough as even to bear rubbing with the finger while wet.

The plate is coated with collodion in the ordinary way, and, after resting a few seconds, is dried by heat over a spirit-lamp or otherwise. After the plate has been made quite warm, it is put aside in the dark to cool and to absorb a certain amount of moisture from the atmosphere. This may take five or ten minutes. If the plate is used too soon the result is unsatisfactory; but, on the other hand, it will not do to leave it long enough to become sensibly moist. Something will probably depend on the particular sample of collodio-chloride.

The exposure required is about five or seven minutes to the autumn sun. On a hazy day something more may be required; but if there are many clouds about, the experimenter, unless naturally of a good temper, will do well to postpone his operations.

On removal from the frame, the plates may be placed in a dish of water until it is convenient to finish them. They are fixed, without any toning, in a dilute solution of hyposulphite of soda, such as is used for paper prints, and then carefully washed. The most effective washing is a combination of rinsing and soaking. My practice is to rinse the plates under the tap for half a minute in order to remove the greater part of the hyposulphite of soda, and then to allow them to soak for an hour or two in water changed two or three times. After a final rinsing the plates may be set up to dry.

Gratings finished in this way give excellent definition, but the spectra are rather deficient in brilliancy. This defect is of less importance than might be supposed; for in order to see the finer fixed lines, sunlight is in any case indispensable, and with sunlight there is usually illumination to spare. Nevertheless, as gratings are likely to be largely used for the purpose of popular illustration under circumstances where artificial light must be employed, I am glad to be in a position to recommend a simple mode of treatment, by means of which the brilliancy of the spectra may be materially enhanced. For this purpose it is only necessary to treat the fixed and washed impression with a solution of corrosive sublimate. When the whitening effect is complete, the plate must be again washed, and then set up to dry. Considered as a photographic transparency, the grating is reduced rather than heightened in intensity by this process. The cause of the improvement of the spectra will be touched upon presently. These mercury-treated gratings cannot be varnished without sacrificing most of the advantages of the method. I have occasionally applied the same treatment successfully to tannin plates.

When not in use, the finished gratings should be kept in a dry place and protected from dust and other atmospheric deposit. For this purpose they may be put away wrapped in paper. For a short time there is no objection to leaving them standing, face inwards, against a wall; but a better plan is to place them, face downwards, on a flat and thoroughly clean piece of plate glass.

\* Continued from page 232.

The originals from which I have hitherto taken copies are three in number. Two are by Nobert, and contain respectively 3,000 and 6,000 lines, in each case covering a square inch (Paris). On a casual inspection the second, apart from the greater number of its lines, would be preferred, as presenting a more even appearance. The 3,000-line grating is divided into three parts, giving spectra of differing degrees of brightness, corresponding, no doubt, to a variation in the cut of the diamond or other stone employed, a peculiarity which is faithfully preserved in the copies. But on actual trial it is found that the spectra of the 3,000-line grating are much the best in respect of definition; and the same difference is observed in the copies. The superior brilliancy of the close-ruled grating is thus of little or no advantage for the investigation of the solar spectrum. In order to make good use of it, a higher degree of magnifying-power would be necessary than the definition of the spectrum will bear.

The other original grating was engraved by Mr. Rutherford, of New York, and was kindly lent me by Mr. Browning; it contains 6,000 lines to the inch. Owing to a change of residence, I have not hitherto had an opportunity of testing either the original or the copies on the solar spectrum; but I may observe that in respect of brightness they fall far short of Nobert's. This, as I have already remarked, is not always an objection; and the accuracy of division, on which definition depends, is said to be very superior.\*

(To be continued.)

### MANIPULATING CAMERA.

BY S. T. STEIN.

THE following specification describes a camera which the inventor styles the "Heliopictor," its object being to work the wet process without dark room or tent:—

"The improvements consist in providing cameras designed for taking photographic pictures with a self-containing 'dark room or space in which the several processes of 'sensitizing' the plate preparatory to exposure, and the subsequent operations of 'developing' and 'fixing,' can be performed with facility; the improvements may be thus described:—

"A recess or space is formed in the camera which is designed for having inserted therein, in suitable slides, a hollow case or receptacle, which I call a 'heliopictor,' preferably made of glass or bitumenized wood or other material suitable for containing photographic chemicals.

"One side of this hollow frame or case is provided with a space into which the focussing or object glass is inserted, and which, when such glass is not there, can be hermetically closed by a yellow glass frame, which is pressed and maintained against the sides of the frame by strong springs; the opposite side of this hollow frame from the object plate is formed of a yellow glass wall, through which the interior of the enclosed space or chamber and the various operations performed therein as hereinafter described can be seen; this yellow glass wall extends from the top to about two-thirds of the distance of the 'heliopictor,' the space below being constructed in the form of an enclosed receptacle for containing chemical liquids.

"The side of the 'heliopictor' is provided with a hole through which the faucet or stem of a glass or bitumenized funnel supplied with a tap can be inserted; the said hole, in order that it will be capable of always excluding the light, is provided with a spring closer or flap.

"The mode of using the camera will now be understood on reference to the following description:—When the object to be taken has been clearly focussed, the object plate is withdrawn, and the glass plate upon which the photograph is to be taken is then prepared for this purpose by pouring over its surface a solution consisting of the following components, viz., 100 parts of water, 25 parts of fresh mixed albumen, 10 drops of glacial acetic acid, and half a part of iodide of potassium; it is then substituted for the

object plate previously withdrawn, in which position it forms one side of the enclosed receptacle or 'heliopictor.'

"At this time the bent faucet of a glass funnel is inserted in the side hole of the 'heliopictor,' the side spring slide or shutter being raised for this purpose: the funnel in this position is in direct communication with the lower portion of the 'heliopictor,' into which is then poured out of a qualified graduated measure as much nitrate of silver solution as will fill the space below the view or yellow pane; at this time the communication between the funnel and the 'heliopictor' is closed, and the case quickly turned into a position that will cause the silver solution to run over the surface of the collodionized glass plate, which operation is continued until the streaky appearance first caused by the flow of the silver solution over the plate assumes a uniform surface. This and the other processes requiring a chemical light are all controlled by the operator through the medium of the yellow glass or view pane.

The 'heliopictor' with the prepared sensitized plate is now inserted into the slide of the camera, the dark slide of which is then raised, and the sensitized plate exposed to the object it is intended to portray in the ordinary manner.

"After sufficient exposure the slide is again closed, and the undeveloped plate is placed in a position to receive the solution employed for developing the picture. The space in the 'heliopictor' occupied previously by the sensitized plate now receives the yellow frame first mentioned through which the light is reflected, and which enables the operator, when the developing solution is poured into the 'heliopictor' (in the manner previously described when sensitizing), to determine when such process has sufficiently advanced, at which time the 'heliopictor' is placed in a vertical position and the liquor allowed to run out of the receptacle, to effect which the faucet and funnel employed for admitting the solution is reversed or turned downwards.

"The 'heliopictor' is then, by placing the funnel in its first position, supplied with fresh water for washing the developed picture, the water as used being constantly discharged therefrom by the reversed or downward turn of the funnel.

"When sufficiently washed the picture is fixed with hyposulphite of soda or other fixing solution, and then well washed in the usual manner.

"The 'heliopictor' previous to the fixing process is ready for employment again."

### ORNAMENTAL BORDERS FOR PHOTOGRAPHS.

BY WM. GAREY.

THE following is a method of preparing ornamental borders for photographs by lithography, or other similar method, previous to albumenizing the paper:—

"My said invention has for its object to obtain improved and superior effects when photographic printing is combined with ordinary printing. A carte-de-visite having the portrait encircled by an ornamental lithographed border is an example of the kind of combination referred to; there are, however, various other well-known ways of combining the two printings.

"Hitherto the common way of combining the portrait or subject photographed on albumenized paper with a lithographed or other separately printed border or device has been by cutting it out and pasting or fixing it on card or paper having on it such border or device, such combination presenting a patched and comparatively defective appearance, owing to one part being more highly glazed than another.

"By my present invention, however, the border or other ornamental or accessory device is lithographed or otherwise printed on the paper that is to be subjected to the photographic process, but previously to such paper being albumenized. The paper is then albumenized in the usual way, and so that the albuminous coating covers the printed part as well as any unprinted portion. The photograph is then produced in the usual manner, care being taken to have it arranged, as regards position, so as to combine and agree in the desired manner with the previously printed device. In this way, when the whole is completed, the entire surface, both printed and photographed, will have a uniform glaze or finish.

"Having thus particularly described my said invention, and the manner of performing the same, I have to state that what I believe to be novel and original, and claim as the invention secured to me by the hereinbefore in part recited Letters Patent is, the preparing of paper for photographic purposes by printing ornamental or accessory devices on it previously to its being albumenized, as hereinbefore described."

### THE PHOTOGRAPHIC SOCIETY OF LONDON.

THE Photographic Society of London has once more a body of officers: twenty-two gentlemen have been elected, by the popular voice, to fill the vacancies in the council and in the presidential and vice-presidential chairs, and, so far as the acclamation of a somewhat scanty meeting may indicate, the elections gave general satisfaction, as, indeed, an election by universal suffrage could scarcely fail to do. One or two protests—as in such cases generally happens—were made to the effect that an election by the vote of the members at large was not in accordance with law. It was not. There was no law applicable to the case. The original law-makers had never contemplated such a contingency as that which has arisen, and they had not provided for it. If there had been any law applicable, it would have been difficult to apply it, as no body of officers with power to put the law in operation existed. Apart from the general collapse which rendered an appeal to the society at large desirable, at the moment when Mr. Hooper's resolution was passed it had become imperative. Every officer in the society, old and new, of certain legal standing, or doubtful legal standing, with the exception of Mr. Spiller and Mr. Davis, had resigned, and they had announced their resolve to abide only by the result of an appeal to the society at large. No quorum of officers existed to give effect to any law; and, in fact, as Mr. Fry remarked on Tuesday evening, without a government the law was a dead letter. In this state of paralysis or negation of the law, the obvious course—the constitutional remedy, as Mr. Bird phrased it—was to appeal to the source of law, those by whom, and for whom, all law is made, and by virtue of whose will the law alone can derive force. Under any circumstances, it is now generally admitted by all having the interests of the society at heart, that voting for officers should be the right of every member; but under existing circumstances it has become especially imperative. An unhappy feud had arisen in the society, chiefly amongst the local members. We put aside here all discussion as to its origin and merits. This feud had grown in bitterness, and the meetings had become the battle-field of contending factions. As the agitation was chiefly local in its origin and operation, any election or any new legislation decided by personal voting, at a local meeting, must have failed to restore harmony, and was only calculated to intensify the bitterness. This appeal to the members at large, which a general collapse had rendered imperative, was also the most expedient thing for healing purposes which could be conceived, and we have little doubt the majority of the combatants on both sides will lower their points and accept the issue gracefully.

We have not, as we have said, any intention to prolong bitterness by reviving discussion on the origin or conduct of the agitation of the last few months; but it may be instructive to note the tendency of public opinion as displayed in the voting. About three hundred voting papers were sent out, and, so far as we can learn, less than one hundred and twenty returned, the issue very much resembling that common in parliamentary elections. Nearly two-thirds of the members, from various causes, failed to vote. Absence from home, miscarriages and accidents, unintentional neglect, and procrastination will account for some, but there can be little doubt that apathy accounts also for a very large proportion; and the apathetic members, it is tolerably certain, have not had much sympathy with the late agitation. Those who have voted are manifestly the active members concerned in the interests of the society, and ready to maintain them. The gentlemen they have elected consist of fifteen members of the old council, two independent members who have most efficiently supported the old council in recent discussions, one opposed to both sides, and three or four of the requisitionists.

The gentlemen elected have now no smooth path before them. Whoever goes into office stands practically pledged to energetic action in securing a new code of laws, a task of no light magnitude. It is to be hoped that all those elected will accept the office, and address themselves to the new duty, forgetting every heart-burning, and working harmoniously together to restore, as far as may be, that prosperity of the society which has been so seriously imperilled.

### THE COLLODIO-CHLORIDE PROCESS.

THERE appears to be a common agreement amongst the majority of photographers, to the effect that the collodio-chloride of silver process yields results of unequalled beauty, the prints possessing a delicacy and richness not attainable on albumenized paper. There appears to be, further, an agreement amongst all who have given the process any extended trial, to the effect that the results are more permanent than prints on albumenized paper. But there is also a wide-spread opinion to the effect that the process is difficult and uncertain, and involves considerably more trouble than albumenized paper.

Of the beauty of the results there cannot be a doubt. The exquisitely charming prints sent by Mr. Bruce to the last Photographic Exhibition and the present International Exhibition have been the subject of universal admiration, scarcely less on the ground of their peculiar richness, delicacy, and distinction of tone as prints, than on the score of pictorial excellence. Those who are familiar with Mr. Bruce's daily work in portraiture (for all his work is printed by this process) know that the results are not one whit inferior to his exhibited pictures. The examples exhibited by Mr. Hooper, by himself, and by others, attest the same excellence of quality. The exquisitely beautiful little gems exhibited by Mr. Faulkner at the present moment in the International Exhibition are, we have learnt within the last few days, printed by the collodio-chloride process. The superior permanency of the results appears to be attested by all whose experience gives value to their testimony. The argument advanced to the effect that a few pictures, carelessly produced, had faded, is scarcely a weighty one, and, oddly enough, is precisely the same argument which has occasionally, and equally fallaciously, been advanced against the carbon process. Some of the early examples of carbon, from imperfect manipulation, cracked away from the paper, and it was triumphantly pointed out, by conservatives of silver printing, that carbon prints were unstable. Some other early examples were produced in fugitive pigments, and it was still more triumphantly pointed out that they had actually faded! In both cases, of course, the defect was in the

worker or materials, not in the process; and so it has been on some occasions in relation to the collodio-chloride process. In several cases we have known that fading has occurred, and that from the simple and obvious cause that albumen, the chief source of fading in ordinary prints, was used as a substratum for the film of collodio-chloride, in opposition to our frequent cautions against it. Any process may fail in a variety of ways if imperfectly worked; but this is no argument against the process.

The general experience and the general testimony agreeing, then, as to the advantages in beauty and stability of collodio-chloride pictures, the real difficulty which stands in the way of the process consists in the real or alleged difficulties by which it is surrounded. We may remark, *en passant*, that we have at times heard the fact that a process was somewhat difficult to work, alleged as an argument in its favour, as the difficulty would keep it in good hands, instead of allowing it to become common. That patient and careful men do succeed, is illustrated by the fact that Mr. Bruce uses no other process in his daily business as a portraitist. That many others succeed is illustrated by the fact that Herr Obernetter manufactures and sells a very large quantity of collodio-chloride paper, having some years ago, as he informed us, used three hundred pounds weight of silver in preparation of the emulsion. In America the process is very extensively used for printing on opal glass, one house alone producing about two thousand opal pictures monthly by its aid. But still the fact remains that in this country it is comparatively little used, and those who have tried it have found difficulties sufficient to deter them from its extended adoption.

Many of the difficulties described are, we are satisfied, unnecessary ones. Prior to our introduction of the process to photographers, at a meeting of the Photographic Society, we had worked it out carefully during six months, trying some hundreds of experiments, and producing some hundreds of prints, many of which we now possess in a perfect state of preservation. As every step we had to take was new, without precedent to guide us, we naturally met in the untrodden path with almost every difficulty possible in the process. The first trouble was lack of vigour. Chloride of silver alone gave a weak grey image: with excess of nitrate, and on an English paper sized with animal matter, we obtained vigour enough; but the free nitrate combining with an animal size, suggested doubtful permanency, and we felt that it would not do to rely upon the quality of the paper for vigour: it must be obtained from the emulsion itself; and just at this juncture, Mr. Bovey suggested to us the use of citric acid, which met the difficulty at once. Other organic substances were tried; but, on the whole, we still prefer citric acid.

The next series of difficulties had reference to the toning. In the ordinary toning bath the action was too rapid, and blue or grey blacks the result. An old acetate bath answered well; but finally we worked out the method with sulphocyanide of gold, which has been since adopted by almost all collodio-chloride workers. Another difficulty arose from a tendency to irregular patchy toning. This arose from two causes: one, the extreme sensitiveness of the surface to every touch of the fingers, which produced irregular markings in the toning; and another arising out of the use of unsuitable impermeable collodion, which absorbed water irregularly, and so caused uneven toning. Both these sources of difficulty are easily met by proper precautions.

The chief difficulty which seems to have beset many experimentalists was one with which we had but little trouble: we refer to the tendency in the paper to curl up when in the toning and fixing solutions and washing waters, the film occasionally splitting away from the paper. This tendency appears to characterize the examples of paper in commerce prepared by Herr Obernetter and others, more frequently than those samples of

paper which the experimentalist prepares for his own use. The cause is not difficult to trace, and the remedy should not be difficult to apply. The cause is two-fold: the use of a somewhat horny contractile collodion, and the use of a soft absorbent paper to sustain the film. The result in such a case is inevitable. The horny, repellent film of collodion is not readily penetrated by the water, and never freely absorbs it; but the soft, absorbent paper, readily absorbing water, naturally swells and stretches on that side which is not protected by the impervious collodion; and as the other side cannot as readily stretch, the curling up is inevitable. The remedy is simple, and consists in the use of a less repellent collodion, and of a less absorbent paper. The chief defect we have found, in commercial samples of collodio-chloride paper, has consisted in the use of a common absorbent paper, which has led to the trouble in question. With a firm, hard paper, not more greedily absorbent of water than the collodion with which it was coated, no such difficulty could possibly occur; and we should strongly advise any manufacturer of such paper to incur the cost of a paper of better quality, as well as to use care to avoid collodion over-horny and repellent, however desirable collodion of that character may be in securing a brilliant surface.

So far as we know at the present time, the collodio-chloride paper of Herr Obernetter is the only paper of the kind which can be obtained ready for use in this country; but there are and have been several manufacturers of such paper on the Continent. Some months ago we were favoured by Mr. Archer Clarke with a sight of an exceedingly perfect example of collodio-chloride printing produced in Lübeck, and also with a perusal of a letter and circular by Herr Linde, who prepared the paper for sale, and was also willing to impart his instructions for securing perfect results for one hundred thalers (in round numbers about £15). We subjoin some extracts from the circular in question which may interest our readers, as suggesting possibilities, although, of course, some of the statements must be taken *cum grano salis*. Herr Linde says:—

My paper is, in truth, free from all the defects which have caused many of my colleagues to give up the use of collodion paper, and to revert to the albumen paper, in spite of all the deficiencies which attach to the latter as compared with the former. The enamel paper remains flat during the toning and fixing, and does not roll up; it does not peel off; it yields in the gold bath each tone, from sappy brown to bluish black; it has no iron stains; it is very delicate and brilliant, and it is equally good in all parts; it is very safe against injuries; it keeps for from six to eight weeks perfectly white; it permits obliterations, retouching, and colouring, like albumen paper. The impressions on this paper do not fade, and do not afterwards become spotty, because the hyposulphite of soda that is applied in a weak solution is easily washed off, and silver albuminate could not be formed.

The *brilliance* and *fineness* of the images produced on collodion paper, which repeat the most subtle delicacies of the negative in a way that albumen paper never can do (since, in the first, the image is received only in the film of collodion, and does not penetrate into the paper stuff), are certainly acknowledged.

#### MANAGEMENT OF THE COLLODION PAPER.

Like every photographic paper, the enamel paper also ought not to be touched on the upper side with perspiring fingers, because in that way reddish brown spots are generated. If we have touched the negative with sweating fingers, we must rub off such marks with cotton, or else corresponding red spots will show themselves on the images.

The negative that is to be adopted must be finely worked up, and not hard. A good retouching with a pencil is advisable; some indispensable covering over of the transparent portions occurs upon the back of the negative, for which Berlin blue or brown ochre, or white pigment in a tube, mixed with a solution of gum arabic, are very well adapted.

The printing is done in shadow, not much darker than the completed images are to be. The enamel paper is very remarkably more sensitive to light than the albumen paper. The impressions must be washed out in spring or rain-water three times changed, and then toned in the following gold bath:—

No. 1.—Sulphocyanide of ammon. ...	80 grains
Hyposulph. soda ...	7 "
Distilled water ...	6 ounces.

No. 2.—Neutral chlorido of gold ... .. 4 grains  
Water ... .. 6 ounces.

The solution No. 2 is mixed in equal portions with solution No. 1; in fact, No. 2 is poured into No. 1. The impressions are placed one by one into the gold bath, quickly dipped, and, if we are toning several at the same time, they must be moved a little by shaking the vessel. Here it is not advisable to lay many prints one upon another, because the liquid cannot affect them all equally, and the prints receive red spots; nor can the work be so well washed over. The toning is brought to an end as soon as the desired colour is attained. A few trials will best instruct as to the proper moment.

The toning process goes on tolerably rapidly until the solution becomes milky. By the addition of solution No. 2 we may again revive the toning solution; but it is more important to make a new mixture, because, by the employment of quite small vessels, we use a less quantity, and thus the consumption of gold remains a scanty one. We may admit the hyposulph. of soda from solution No. 1, but then the images more easily become blue. After the toning we place the impressions in pure water, and then fix them in a solution of—

Hyposulph. soda ... .. 1 part  
Distilled water ... .. 20 parts.

We wash out with water, that must often be changed, and, as customary, cut out the images, when half moist, with a knife, mount, and press them.

The erasure of spots takes place as with albumen paper. The addition of gum is advantageous and agreeable for painting; and working by Grashoff's prescription (water colours strongly mixed with gum) is very easy. Here it is to be recommended, after the local colours have been laid on, to pour thin collodion over the image, and then further to work. The wash of collodion protects the first coat of colour from obliteration during the subsequent painting.

By way of supplement, we rub the prepared images with the well-known waxen paste (wax and turpentine, or lavender oil), in order to render the retouching invisible, to prevent its being wiped off, and, in the case of retouching with gum, to prevent the impressions from sticking together. Some photographers also once more wash the images with plain collodion.

#### A FEW REMARKS ON THE PRESENT ASPECT OF SILVER PRINTING.

BY W. T. BOVEY.

No longer embarrassed by the distracting influence of novel discoveries, photographic experimentalists, in lieu of wasting precious time in "prospecting," are wisely retracing their steps to explore anew the old fields which were long since traversed over in haste. And it is somewhat curious to note that a printing process, persistently said to be doomed to oblivion by the beautiful and ingenious invention of Mr. Swan, is one which at the present time is receiving the largest share of attention; and thus is amply borne out the soundness of my prediction when, years ago, I expressed belief that silver printing and carbon printing were destined to fill independent positions, each taking its place of usefulness, that cannot by either be exchanged or supplanted. The magnificent examples of enlargements produced by the Autotype Company at Ealing indubitably show that in such work carbon printing has turned into its legitimate channel. And the Woodbury-type, by its rapidity of production and beauty of results, has obtained a firm hold on popularity. The Heliotype process has its successful future, and only awaits enterprize and ingenuity to remove its present defects. Whilst silver printing, as chief favourite, stands unrivalled in the perfection of its production, and has now new hopes of the stigma of instability attached to its character being removed by the new turn taken in the review of remedies in that direction now engaged in by experimentalists.

In connection with silver printing, a German writer has recently favoured us with his opinions on the matters of weak and strong sensitizing solutions, the latter being strongly advocated by the writer in question; and, to a certain extent, I fully concur in his views. There can be no greater error committed than to suppose that the use of a starved silver solution is either economical, politic, or discreet. On the other hand, in these days of heavily coated albumenized papers, strong silver baths cannot be

resorted to without danger of producing the evils, in a highly aggravated form, which they are expected to obviate, as the process of "coagulation," if too suddenly and thoroughly accomplished, precludes the necessary action of absorption, and a weak, spotted image, on a highly-polished surface, is the result of the mistake.

A bath composed of—

Silver ... .. 40 grains  
Nitrate of soda ... .. 20 grains,

might be used with safety until the supply of silver is reduced to thirty grains. Below that it is unsafe to go. Probably the best test that can be applied is to make a pause when in the act of floating the paper, and until the brief stoppage induces the production of a line, as far as the supply of silver is concerned, all might be considered well.

The next matter relating to silver printing which appears to receive attention is one of spotting—a subject on which I have already exhaustively written as far as the spots met with in ordinary every-day experience are concerned. There is, however, one form of spots that still requires investigation, which, on a recent occasion, was the subject matter of an earnest appeal for help, in a letter to the *News*. White spots, small in size, and irregularly scattered over the print—thus were they described; and with some amount of eagerness I scanned the answers tendered by sympathetic correspondents to the prayer addressed to them for aid. By some curious mischance all the communications in question seemed to miss the true mark; and such being so, it might be worth a little of space to describe what I believe to be the immediate cause of the perplexity-raising mischief. It should be remembered that those minute spots are of two kinds, and originate from two distinct and separate causes. The first (occasioned by defects in paper), if viewed with the assistance of a microscope, reveal the presence of metallic centres around which are described circles of insoluble hyposulphite of silver. These occur chiefly in the whites, or in those tones which graduate nearest white. Where the printing is deep, the reduction of the silver to a sub-salt, nearest the metallic state, precludes the possibility of yellow white spots generating. The form of spotting which seems to escape the grasp of understanding, and to which I have already alluded, is one, however, similar in form to those just described, but altogether different in colour and origin. In such as these no metal or other centres exist. They are simply white splashes that form because of the removal of the silver by some eating process; and this action, I have learnt from careful observation, is set up by an imperfect system of washing in metal vessels, the syphon abomination being the chief agent in destroying the chance of permanency that its use is resorted to for the purpose of procuring. Theoretically, an ebb and flow of water in the washing arrangement certainly appears to be the only method that can insure success in practice; but actual experiment goes to prove that, although perfect in theory, it is found to be far from perfect when tested by an actual trial. If we watch a batch of prints as the water is escaping through the syphon, we perceive them twisting in the eddies, now on one side, anon drifting toward the other, until, with a sudden motion, they seem to leap toward the side of the trough, against which they cling, and are soon afterwards left dry until the return of the replenished water.

Now, as long as the washing apparatus is new, or has had brief use, no injury arises to the prints during their season of suction; but when, with constant use, a deposit forms around the side—or, rather, I might say, when a crust is formed by a combination of the metal with the sulphur—there lurks danger unsuspected, and as the spots thus wrought in the prints are not always directly visible, their cause cannot even be guessed at. Wooden troughs for washing purposes are by far the safest if scrubbed daily, and even these should never have any metal placed

within contact distance of the prints; indeed, the safer and by far the better plan is to ignore the syphon altogether, as by experiment I have found they work more harm than they effect good. An india-rubber tube leading the supply at the bottom, and an escape pipe to conduct the water from the top, insures non-contact, and as thorough a washing as the prints can get by any other automatic method. The best means, however, of eliminating the hypo are such as are brought about by chemical agency.

For some time past I have been using a very perfect and reliable mode, the modification of which alone is of my own contriving, and unfortunately I am precluded from imparting particulars by the author of the process, who, I doubt not, will ere long remove the bond of secrecy when he is brought to see the folly of making it the subject of a patent. One lesson learnt from the practice of the secret means referred to I might, without dishonour, dwell on. Among other virtues, the chemical agency I now use for removing the hypo has the remarkable property of seizing upon and spoiling improperly fixed prints. Noticing this peculiarity, I proceeded to experiment, and have discovered that the whites of a print take longer to fix than the other portions of the picture. A darkly printed vignette will be fixed in ten minutes, whilst the white margin requires twenty. The moral gleaned from this has induced me to extend the time of immersion in the hypo for prints with extensive whites, and I believe the fruits have repaid the cost of time. Fading prints commence to fade in their whiter parts. Here we have an explanation.

#### MY EXPERIENCES IN PRODUCING NEGATIVES IN PLUMBAGO.

BY W. B. WOODBURY.

BLACK-LEAD, a substance hitherto only associated with fire-grates and stoves, is about to play an important part in photography, and will soon be one of the most useful articles the photographer possesses.

It is now some eight or twelve months since Messrs. Geymet and Alker, of Paris, published a small work on the collotype processes, in which ample directions were given to produce a reversed negative by the use of plumbago. Extracts from this work were published in our journals, but, like new things, I suppose, very few people took the trouble to try it; and it is only now that M. Obernetter, of Munich, has received a gold medal from the Vienna Society for publishing his process, that the public are beginning to open their eyes to the great benefit of this method over all others.

There are many ways of reproducing negatives—by copying, by contact with wet or dry plates, by carbon, albumen, &c.—but which all require a double process; and there is always a something about them in which the charm possessed by the original negative is lost.

Now, in the process of reproduction of the negative direct from the negative, with no positive interference, there is no such loss—in fact, by careful manipulation, a negative may be reproduced, a print from which and one from the original being placed side by side, the producer himself could not distinguish the difference. But that is not all. A negative having every detail, but lacking in brilliancy, can be reproduced with the very brilliancy it lacks, and so be very much superior to the original. Again, from a too dense negative, one of the right printing density can be obtained. But in these days of what may be termed fancy printing, the results of which are only obtained with considerable time and labour, how great is the boon!

Suppose we wish to obtain an oval vignette carte on a black ground, this would first involve the careful vignetting of each print, then the use of a mask to shade the centre while the outside darkens. How much time would be saved were all these requirements in the negative itself!

In the plumbago process this would be accomplished as follows:—The prepared glass would be first exposed under the negative, a vignette glass or other method of vignetting being adopted; the exposed plate would then be covered with an oval piece of black paper, and the outside exposed to light. On developing this picture with the plumbago, we should possess a negative giving at one operation all we require, and what would otherwise have taken considerable care in manipulating. By carefully developing from the centre, outside, a vignette picture similar to those produced in Russia would be the result. But perhaps one of the most important uses of this process will be the production of combination negatives instead of combination prints, which means immense saving of labour, these sort of prints having always represented such an outlay of time as to be necessarily expensive. One thing to be borne in mind is, that in this process things are all reversed, the shorter exposure giving more detail, and the longer a hard, chalky effect; but still there is great latitude, as a plate slightly over-exposed may, by leaving in a damp place, be made to develop all right.

My first attempts were made some six months ago on obtaining a copy of Geymet and Alker's work, but the results I got were by no means encouraging. I followed the instructions to the letter, but my results were coarse, showing lines of the brush over the parts that should have been transparent. Having, however, had, during a late visit to Germany, an opportunity of seeing some of Obernetter's results, I determined to try again, and this time my trials were very satisfactory, but this time I did not adhere strictly to the instructions; I omitted the breathing on the film, and found out that this had been the sole cause of my earlier failures.

To any one trying this process, let me give him this caution: never to breathe on the plate, except in rare cases, as bringing up an under-exposed foreground, &c. It is, I believe, impossible to moisten the plate evenly by the breath; far better to let the plate remain longer in a damp place, until it gets in to the proper state.

The solution I used was—

Gum	...	...	...	1 drachm
Glucose	...	...	...	3 "
Glycerine	...	...	...	10 drops
Bichromate of potash	...	...	...	30 grains
Water	...	...	...	2 ounces

filtered carefully through blotting paper while warm, and kept in a bottle for use. No cork should be used, but a piece of glass kept on the bottle, as the slightest particle of solid matter getting into the solution is fatal to good results. The plate must be carefully brushed, to remove all particles of dust or fluff from the cleaning cloth, these particles forming a nucleus which, by the repeated passing over of the brush, forms a black spot in the negative.

I cannot say how long this solution may be kept, but I found it as good after a week as when freshly prepared; and as the ingredients are so inexpensive, and the solution so easily prepared, no trouble need be held on that score. One of the difficulties of the process is the tendency of the solution to run away from the glass when inclined to pour off the surplus: and, curiously enough, the more carefully the glass is cleaned, the more the solution seems inclined to leave it. Doubtless something might be added to prevent this, but by using the solution warm, this is not so likely to occur.

The glass, cleaned and carefully dusted, was coated with the mixture, and the surplus being poured back, was held over a Bunsen burner till dry, a piece of blotting-paper being drawn along the two downward sides to prevent the solution thickening at those parts. When dry, and still warm, it was placed in the frame in contact with the negative, an exposure of between two and three minutes being given in the sun; on taking out of the frame the plate was left about five minutes, and the plumbago softly

applied until the image gradually obtained the required density. It was then coated with a thin normal collodion, and dried; when thoroughly dry, placed in a bath of water six parts, and hydrochloric acid one part, which instantly dissolved the yellow of the bichromate. When again dried, the negative was varnished, and the operation concluded. By this means were produced the negatives I had the pleasure of showing at the last meeting of the society.

There are one or two points that I noticed in my short experience that may be useful to those who try this method. First, the plumbago negative should not be developed long enough to appear as dense as the original, otherwise it will print too hard, the deposit being of a more non-actinic nature than that of the silver. I noticed in all Obernetter's reproductions that they were apparently much thinner than the originals, although prints from them were alike.

An underground room is best adapted for the development, the greatest freedom from dust being an absolute necessity. An exceedingly fine sample of plumbago is necessary: that I used was one prepared by Messrs. How for coating electrotype moulds. A very fine sample is also prepared by Messrs. Newman, of Soho Square.

Always use a glass rather larger than the negative, as there is a tendency to give the centre an over-dose, and neglect the edges. I have not tried taking the film from the glass to reverse it for ordinary printing, as my aim was to produce a reversed negative, but I apprehend no difficulty would be experienced, a thicker sample of collodion only being necessary.

One other advantage in these negatives is, that they are permanent, which cannot be said of silver negatives, as so many are found to darken by much printing; and if there is any one substance more permanent than others, I think it is black-lead.

#### ON THE PRODUCTION OF ENLARGEMENTS UPON ALBUMENIZED PAPER BY DEVELOPMENT.

BY CARL MATZNER.\*

*Preparation of the Paper.*—In the first place, I prepare a bath of nitrate of silver, dissolving one part of silver in eight parts of water, and to it I add, as soon as the crystals have been completely dissolved, the tenth part of citric acid, previously dissolved in a little water. During the gradual addition of the acid the bath is continually shaken.

I choose good stout albumenized paper, and immerse the same in the silver bath so that the back, as well as the front, becomes impregnated with the solution. After three minutes, I hang the sheet up in a perfectly dry place, and allow it to desiccate slowly. The paper is more carefully kept from the light than ordinary sensitized paper, for it is somewhat more sensitive. It may be prepared a day or two before it is required, for the acid in the bath allows of its preservation in good condition for a week or more.

*Printing.*—The printing is done either in a pressure-frame, or in the solar camera by enlarging. For the latter case this developing process is especially suitable. I allow the printing to go on for a fourth or fifth only of the usual time, so as to obtain a weak, but perfectly visible impression, and then put the print away in the dark room for further treatment hereafter.

*Development.*—The development may be conducted the same day, or at a later period. If the pictures were treated with gallic acid solution—even with the addition of acid—the whites would change to yellow, and finally become brown. I protect myself from such a change in the following manner:—I first lay the sheet, which has

been partially printed, in a clean dish large enough for the purpose, in a well shaded apartment, and pour over it some distilled water, just enough to cover the bottom of the dish and wet the sheet on both sides. The addition of a few drops of the silver bath above described to the water in the dish is of great advantage. I tilt the dish a little, so that the liquid therein runs to one corner, and add (when a whole sheet is in the dish) an ounce or an ounce and a-half of glacial acetic acid to the liquid. This is then allowed to run under and over the picture, and to penetrate it for about five minutes. After this I proceed with the development. The albumenized paper has been rendered transparent by the acetic acid, and the great point has now been achieved, for it is possible to watch the action of the gallic acid from the back of the print.

I slowly pour over the picture a concentrated solution of gallic acid, which has also been acidified with acetic acid, and gently move the dish to and fro. The picture slowly develops, and, after about half an hour, becomes very vigorous and dark, if the temperature is not too low. In the course of the operation one can see whether it is possible to secure the right amount of density. If this cannot be attained, then a few drops of the first-named silver solution are added, to give intensity. As the fixing agent diminishes somewhat the intensity of the picture, it should be thoroughly developed. It is washed thoroughly, until all the chloride of silver and the acetic acid have been altogether removed—at the last with distilled water—after which the toning is proceeded with.

*Toning.*—Any toning bath with which one is familiar may be employed; but it must be used only half as strong as usual. I pour the water off the picture, and pour on the toning solution, rapidly agitating the liquid the while. On the first apparent signs of a change of tone I take the picture out, and dip it into a hyposulphite bath ready to hand (one part soda and twelve parts water), in which it is thoroughly fixed. Finally, the picture is carefully washed as usual.

To enhance the tone of the pictures, a little gold solution is added the day before to the fixing bath, the latter being shaken the while. The process is a little costly, but the pictures produced are of great value. Gold solution is added until the fluid becomes quite milky. The same bath may be employed many times before it becomes unserviceable.

#### Correspondence.

##### LANTERN IMPEDIMENTA.

DEAR SIR,—Seeing in the NEWS your readers going in for "trouble" *in re* oxyhydrogen light, and having worked the same at our theatre here and various places for years, let me save them wasting money.

Don't buy any bags and don't carry any weights. I will give my plan to your readers in the rough. The contrivance is

all in one, and lighter altogether than one weight. The only thing you want when you get to your exhibition room is water;

\* Read before the Vienna Photographic Society.

you can get that anywhere. Sufficient to fill a vessel the size of a milk churn will last some hours.

To work it, half fill top compartment and both lower ones with water, and screw in plug in hydrogen side. Connect top tap to gas pipe with flexible tube, and turn on bottom tap: water goes out, gas goes in.

Make the gas straight from retort, in oxygen side, which saves purifier. As gas goes in, water comes up pipe, a short length combustion tube. You can see what is going on. In working, as the gas is used from two top taps, the water in top takes its place. When you have done, throw away water, and pack things in top, all one package. Taps should unsew, then they don't get knocked off.

LEO.

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

The adjourned special meeting of this society was held at the Architectural Gallery, Couduit Street, on the evening of Tuesday, the 19th inst., Mr. JOHN SPILLER, F.C.S. in the chair. The minutes of a previous meeting having been read.

Mr. PRITCHARD pointed out that they scarcely accurately recorded the fact that Col. Wortley had moved an amendment on the first resolution passed, and, after a brief conversational discussion, the minutes were confirmed.

The CHAIRMAN stated that the committee entrusted at the last meeting with the duty of carrying out the elections had been engaged for two hours in examining the balloting papers, and would complete their duty and be able to announce the elections in the course of about an hour.

Mr. HUGHES, in the meantime, wished to enter his protest against the whole proceedings as unnecessary and illegal. There was no need to appeal to the members at large: the law provided for the election of officers by the voting of persons present at a meeting duly announced. The resolution was not in accordance with law, and the general appeal was not in accordance with law. Himself and his co-requisitionists were kept at the commencement of these proceedings so close to the punctilios of law, that bitter feeling was generated, and now the law was being ignored altogether. The manner of carrying the thing out was as bad as the thing itself, and he protested against it altogether.

Mr. SAMUEL FRY could not but feel that the protest and objections of Mr. Hughes were groundless and unnecessary. The assertion of precise points of law was surely ill-timed when the society was in a state of revolution. It was idle to talk about law when there was no government in existence to carry any law into effect. The first thing to be done was to obtain, by the will of the members at large, an executive, and then, if any law had been overstepped, obtain a bill of indemnity. He was satisfied that the step which had been taken was the very best which could have been adopted, even if it were not in accordance with law, a point which was by no means certain.

After some further irregular discussion, the committee presented their roturus of the voting, which the chairman read out, giving the following as the officers elected by the general voice of the society:—

*President:* John Spiller.

*Vice-Presidents:* Dr. Mann, G. Whartou Simpson, and Valentine Blanchard.

*Council:* Captain Abney, William England, Sebastian Davis, H. Baden Pritchard, J. H. Dallmeyer, W. Bedford, George Hooper, William Mayland, Dr. Farre, Walter Bird, W. B. Woodbury, R. Crawshaw, Professor Stokes, H. P. Robinson, Col. Stuart Wortley, O. G. Rejlander, F. Howard, Samuel Fry.

The name of Mr. Hughes was also included in the list of elections, but, as he declined to serve, the next highest name in the voting was substituted.

Mr. WALTER BIRD said he thought the society having adopted the constitutional course out of their difficulty, and appealed to the source of law, the members at large, he thought every one ought now to acquiesce in the result, and work together harmoniously for the good of the society; he hoped, therefore, Mr. Hughes would accept his election, and duly act.

Some further conversation followed, in the course of which Mr. Hughes again declined to act. A conversation on the number voting then ensued, the number being variously stated as 105, 110, and 120 by different members of the committee, about three hundred voting papers having been sent out. Mr. Stillman objected that no member of the council had been elected by a

majority of the members. Mr. Bird said that many were elected by a majority of the members voting, some having received as many as seventy votes. A further conversation arose on the mode of filling up vacancies in case any of the elected officers declined to act.

Mr. SPILLER expressed his appreciation of the honour he had received, and bespoke the consideration and forbearance of members in relation to his discharge of the important duties he had to assume. He proposed a vote of thanks to Major Malcolm and the committee who had undertaken the arduous duties in connection with the election. Major Malcolm responded briefly, and after a vote of thanks to the chairman the proceedings terminated.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual meeting of this society was held on the 14th inst., the Rev. F. F. STATHAM, president, occupying the chair.

After the reading of the minutes of the previous meeting, Mr. E. Gacl was proposed and admitted as a new member.

The SECRETARY announced that there was no paper before them that night, and exhibited some pictures he had made several years ago, which led to a conversation on the subject of fading.

Several negatives on Mr. Kennett's gelatino-pelliele were exhibited by that gentleman, after which it was intimated that the next meeting would be devoted to a demonstration of Obernetter's method of reproducing negatives.

The meeting then separated.

## Talk in the Studio.

SUNDAY PHOTOGRAPHY.—We hear complaints from time to time, sometimes on religious grounds, sometimes on the score of illegitimate competition, as to the practice, in some large provincial towns, of Sunday photography. An effort has recently been made in Plymouth to suppress this trade as a nuisance. We make the following extract from a local paper, which shows the issue:—"At the Stonehouse Petty Sessions, before J. B. Willeox and C. Simpson, Esqrs., four charges of trading on Sunday were heard. The first was that of Mr. John Wakeham, for whom Mr. J. E. Curteis appeared. P.C. Coplestone stated that on Sunday, April the 26th, at 10 a.m., he was on duty in Stonehouse. He went to the defendant's shop, and had his photograph taken, for which he paid 1s. 1d. Mr. Wakeham promised to send the cards, but had not done so. Witness was dressed as a marine.—By Mr. Curteis: The negative was a good one. I did not tell Mr. Wakeham that I could only come on Sunday.—In defence, Mr. Curteis submitted that there was no case made out; for the mere taking of a man's likeness was not an offence, because the article was not either finished or delivered.—The Bench did not think that that affected the case in the least.—Mr. Curteis then contended that the business of a photographer did not come within the meaning of the Sunday Trading Act, for it was not a trade, but a profession and an art. An attorney, for instance, would not be liable. Perhaps their worship would say the words 'any other person or persons' were very wide; but he maintained that they did not at all apply in the present instance. The point was, whether the Bench held that a photographer was a tradesman.—The Bench thought that it was a mechanical operation; whereupon Mr. Curteis said that there was, without doubt, a considerable amount of art required to produce a good likeness. He then cited a case which went to show that it did not come within the Act, and in which Mr. Justice Bailey said that he was inclined to think it applied only to manual labour, and the visible performance of some work. He would say, on behalf of Mr. Wakeham, that he had kept his premises closed for seven years, and only opened his side door now in order that he might compete with, and not be outdone by, others. He had never allowed his man to stand at the door and tout, as had some, nor would he keep his premises open at all in the future.—Supt. Brutton explained that he had been specially requested by the authorities at Stonehouse to take proceedings in these cases, for the nuisance was becoming almost intolerable.—The Magistrates, after consulting in private, said they could come to no other conclusion than that the defendant was a trader within the meaning of the Act, and a fine of 5s. and costs would be imposed. They trusted that this would be the means of putting a stop to a state of things which was to be deeply lamented.—Michael Dee, Joseph Hooper, and

William Barkley, all pleaded guilty to a similar offence, but stated their intention not to offend again.—A fine of 5s. and costs was inflicted in each of these cases."

**PROGRESS OF PHOTOGRAPHY.**—It would require a volume to set forth the many remarkable applications and processes, even of comparatively recent date, involved in this astonishing art. Something, however, may here be added in regard to the rapidity of photographic action. It is estimated that 1-27,000th of a second is sufficient to fix the solar image, yet this is a long time in comparison with that in which photographs are taken by the electric light. Experiments have shown that the duration of the illuminating spark does not exceed 1,000,000th of a second, yet a clear and distinct photographic image is obtained by a single electric discharge. By this means may be shown the real form of objects to which a deceptive appearance is given by their rapid movement. Thus, if a wheel on whose side any figure is drawn in conspicuous lines be made to rotate with the greatest possible velocity, the figure will present to the eye only a series of concentric bands of different shades; but let it be photographed by the electric flash while in motion, and the wheel will appear stationary, with the figure perfectly well defined.—*New York Times.*

## To Correspondents.

**CAMEO.**—The spotting or retouching of prints intended to be cancelled with gelatine and collodion presents some difficulty, as, without great care in manipulation, ordinary water colour would be removed by the application of the gelatine. There are two modes of meeting the difficulty: you must either employ a medium with the ordinary water colours, which, on drying, becomes insoluble, or apply some insoluble coating over each retouching mark. Such a medium as "Newman's Preparation" answers well. It mixes readily with the water colour, but becomes insoluble when dry, and prevents the water colour from being softened or washed off when again moistened; or, failing this plan, apply a touch of plain collodion with a camel-hair pencil to each retouching mark. This will protect it on applying the gelatine.

**R. H.**—Much depends on the class of work you intend to do, and on your personal taste and desire. The following are good proportions for a studio, and will answer well if they answer your convenience: about thirty feet long, twelve wide, fourteen feet high at ridge, six or seven at eaves, the sides facing north and south; each end opaque; north side and top, glass, except about six feet at each end and two feet at bottom; south side all opaque, except about eight feet top and side, which will usually be kept covered with blinds, and only used when specially wanted. Common sheet glass will answer well. 2. We cannot recommend makers of lenses and cameras by name in this column; but you will find some names which you can perfectly trust in our advertising columns. The lens you have may or may not be a good one. You can only tell by trying. French lenses are generally variable.

**LEX.**—It is scarcely worth discussion at present. No doubt several members present saw the matter clearly enough, but did not think it worth discussing. Col. Wortley brought forward his suggestion as an amendment, and insisted that it should be put before Mr. Hooper's amendment was moved, as two amendments ought not to be before the meeting at once. It was intended to enact something which the original resolution did not enact, and something of which no notice had been given. If questions of law were worth discussing in relation to the chaos of the moment, Mr. Hooper's amendment was just as legal as Col. Wortley's, or more so, because the absence of notice was due to a disorganised executive, not to Mr. Hooper, who had sent his notice in time. But the truth is, that law being in an absolute state of collapse for want of administrators, an appeal to first principles was the only common-sense remedy. The rude words used we cannot discuss. You will note that we omit such episodes from our report. Such words are occasionally used in the heat of a moment, but they must always be deeply regretted, and have generally been followed by apology, as they were at last week's meeting. In any case, they are better forgotten.

**J. C. M.**—The process is, to some extent, experimental still, and no details have been published. Starch was used many years ago. A thin preparation of starch filtered through muslin is employed. You will find full details of alkaline development in back volumes of the NEWS, and in our last two or three YEAR-BOOKS. It would occupy more space to describe in detail than we can devote in this column.

**AN OPERATOR.**—The circumstance you describe is curious, and it would be difficult to suggest a cause without examining the instrument. Does the tube of the lens project far into the smaller camera? Is the camera properly blackened inside?

**PYRO.**—Our own plan has been to replenish the bath from time to time, as it got low, by adding a forty or fifty-grain solution to the thirty-grain bath, and we have never noticed the working become slower. If it did, we should neutralize and sun very thoroughly. Are you sure that the loss of sensitiveness is due to the bath? It may be the collodion, or the developer, or the cutting off of light by the advancing growth of foliage near the studio. We prefer crystallized nitrate of silver.

**G. B.**—There is no reason why a good half-plate lens, requiring twenty feet between the sitter and camera, should not answer for card portraits. There is, however, one difficulty which may occur: if the atmosphere is thick, or misty, or dusty, it becomes a mass of illuminated medium between the sitter and lens, which sometimes causes a flat, foggy effect. It is also very important to shade the lens from reflections and light of all kind except that reflected from the sitter. 2. An ordinary camera is suitable for taking ferrotypes, but you must take care that the spring at the back of the dark slide does not press upon the flexible plate so as to bend it. You can place a plate of glass at the back of the ferrotype plate, and this will remove all trouble and danger.

**F. M. D.**—Spots of various kinds may appear on prints, and from many reasons. We cannot even venture a suggestion without an example, and we have not received one. There was no print enclosed in your letter. Possibly an empty wrapper we received, referred to below, might have been yours.

**G. G. GRALIN.**—The defect of which you complain is due to the peculiar character of the collodion, which is very horny and repellent. Try adding a few drops of distilled water to each ounce. Try also immersing the plate before it is so fully set, and be very precise in allowing the plate to rest on clean pieces of blotting-paper in the dark slide.

**A. BEGINNER.**—Uneven toning may proceed from a variety of causes. A very common cause is the immersion of several prints in the toning bath, which lie together in partial contact. This will cause uneven patches. They should never be allowed to remain still or stick together. Sometimes handling the prints with soiled or perspiring fingers will cause such unevenness. Sometimes a print will be more fully charged with free nitrate at one end than the other from the position in which it hung in drying, and this will cause uneven toning.

**W. FERGUSON.**—The toning solution is to be kept always in the dark, as light tends to decompose it. The process of toning should always be carried on in a room illuminated with yellow light. Replenish the bath from time to time with portions of another bath made in precisely the same way. If it begins to tone too slowly, a grain or two of the chloride of gold may be added. We regret that we cannot answer questions of this kind by post.

**B. M. F.**—It is a good thing to keep your thick "bottoms" of collodion, rather than use up too close. When a new thin sample is obtained, which gives weak, foggy images, a little carefully decanted from a bottle of "bottoms" is often a very valuable addition. We cannot recommend any especial maker in this column.

**LUX FIAT.**—Light unquestionably tends to decompose a fixing bath after it has been once used, and fixing should always take place in the dark, because the decomposition set up in the hyposulphite of silver formed in the print will almost certainly issue in fading.

**D. D. (BELGIAN SUBSCRIBER).**—The ammonia-nitrate of silver is excellent for plain paper, but we do not recommend it for albuminized paper, as it often involves various troubles, having an especial tendency to dissolve the albumen. The formula most commonly used consists in making a fifty-grain bath, and adding ammonia first until all the silver is precipitated as oxide, and then until it is re-dissolved. It is renovated by adding more of a bath made in a similar manner. We do not recommend boiling it; but the albumen may be removed by permanganate of potash. There is some possibility of the formation of fulminate of silver.

**EMPTY WRAPPER.**—An empty wrapper has been addressed to our office, handed to us by the postman marked "Found in the newspaper box without contents." It may have contained photographs, or documents, or a newspaper; but the absence of contents is not an accident, for it has manifestly been very roughly torn open to remove its contents. The word "Thames" is the only decipherable part of the post mark.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

MR. THOMSON'S ILLUSTRATIONS OF CHINA—THE FIRST DEPARTURES TO OBSERVE THE TRANSIT OF VENUS—PRETSCH'S PHOTO-ENGRAVING PROCESS—MECHANICAL PRINTS.

*Mr. Thomson's Illustrations of China.*—We are glad to hear that Her Majesty has been pleased to recognize the services of Mr. John Thomson, whose work, entitled "Illustrations of China and its People," has attracted her attention. Those who visited last year's photographic exhibition at Pall Mall no doubt remember the grand photographs of Mr. Thomson that ornamented the walls, and which, notwithstanding the unheard-of difficulties involved in their production, were masterpieces of photography. Their size was upwards of two feet, and there were representations of districts but seldom visited by Europeans. Pictures of such grand dimensions and genuine excellence would have been regarded as first-class productions had they represented views in the United Kingdom, instead of having been secured in one of the least travelled countries in the world. The Queen has marked her appreciation of Mr. Thomson's exertions by presenting him with a gold medal, and we heartily congratulate the happy recipient. One of the views that struck us very forcibly was the interior of Nankin Arsenal, showing a *mitrailleuse*, by the side of which were a mandarin and native workman. Another picture, not less striking, was a river scene, with vessels of all kinds moving on the water. They were certainly some of the most ambitious photographs we have ever seen.

*The First Departures to Observe the Transit of Venus.*—A move has already been made by the observers who are commissioned with the duty of observing optically and photographically the approaching transit of Venus. On Saturday last some of the officers who are to proceed to the Southern Hemisphere took their departure, carrying with them astronomical and photographic apparatus to the extent of one hundred and fifty tons. As it will probably take five or six months before some of the party arrive at their destination, the start has been made none too soon, and the vessel that carries them out (the "Elizabeth Martin") only takes them as far as Mauritius. It is the officers for the stations at Rodriguez, in the Indian Ocean, and Kerguelin's Land, about two hundred miles south and east of the Cape of Good Hope, that have sailed, among them being Lieut. Noate, R.E., Lieut. Corbett, C.B., and Mr. J. B. Smith; the latter is entrusted with the photographic duties, while the former will confine themselves to securing optical records. Some Sapper photographers from the Greenwich Photographic School accompany these gentlemen as assistants. There are to follow to these stations Father Perry, F.R.S., who is going to Christmas Harbour; and Mr. Burton, who will discharge photographic duties at Rodriguez. The scientific staff for New Zealand will start in a few days, and will consist of Major Palmer, R.E., and Lieut. Crawford, R.N., as astronomers, and Lieut. Darwin, R.E., as photographer. Captain Abney, R.E., and other officers whose destination is nearer home, will not take their departure for some time. Lord Lindsay's private expedition to the Mauritius is on the eve of starting. All the other scientific bodies but this one are under the direction of the Astronomer-Royal, Sir George Airey, K.C.B., and will carry out the regulations laid down by that gentleman.

*Pretsch's Photo-Engraving Process.*—It is not unlikely that some steps will be taken by the Vienna Photographic Society to continue the work begun by Paul Pretsch some time since, with regard to elaborating a practical method of photo-engraving by the etching of metal plates. Pretsch having now died, and his patent very nearly run

out, it is suggested that, as the invention rests upon a sound basis, it would be well to encourage, in some way, other photographers to take up the method, with a view to perfecting the same. The late president of the society suggests awarding a prize of some value to any one who shall most successfully elaborate Pretsch's photo-engraving process, the results which have already been produced by it demonstrating very clearly that it is capable of yielding thoroughly good work.

*Mechanical Prints.*—The production of mechanically printed photographs seems now to be carried on with great regularity, the demand for pictures of this kind increasing every day. In this country we have the Woodbury process, and the heliotype and Lichtdruck methods, pretty extensively worked; and in France there are MM. Goupil et Cie, of Paris, who occupy themselves with the Woodbury invention; and in Germany, Herr J. B. Obernetter, of Munich, who employs Lichtdruck, representing the principal photo-mechanical printers on the Continent. Between them, these two firms do a great deal of printing by mechanical means, MM. Goupil reproducing engravings and paintings in large numbers, while Herr Obernetter has vulgarized numberless cartoons of various artists. The latter, who may be regarded as the principal photo-collographic printer in Germany, charges at the rate of nine or ten shillings per hundred *carte-de-visite* photographs, supposing a few hundreds are required, or, in other words, half the amount for which the pictures could be printed in silver. The price for Woodburytype of the same size appears to be much lower, about four shillings per hundred being, if we mistake not, the price usually charged. Each process has its own class of negatives, which are more suitable than any other. For the photo-relief method a vigorous *éché*, with soft milky high-lights—not with those of a glaring chalky nature—appears to furnish the best results, while in the collographic method there should be little vigour, and the shadows of a lighter and more graduated character. Thus the most successful portraits we have seen printed in Lichtdruck are those in which the costume worn has been of a light nature, and in which no heavy shadows were to be seen. Thus a man in a light suit of tweed and a grey wide-awake, or a West Indian planter in a puggerec, would be very suitable subjects for the collotype process, which would most likely fail in depicting shadows upon black velvet, deep blacks being generally rendered too fuzzy and flat. In the reproduction of large sized engravings, it may be mentioned, the collotype process is without its equal.

### REMARKS ON THE ASSERTED INFLUENCE OF COLOURING MATTERS ON THE REDUCTION OF SILVER SALTS.

BY JOHN SPILLER, F.C.S.\*

It will be in the recollection of my hearers that Dr. Hermann Vogel announced last year that he had succeeded in rendering bromide of silver sensitive to the so-called chemically inactive rays. Operating upon dry bromide plates washed with coralline yellow and aniline green, the author states that whilst restraining the influence of the rays coinciding with the more refrangible part of the solar spectrum, the sensitized surface becomes directly affected by the luminous rays, and particularly by those situate in the yellow of the spectrum near the fixed lines D. Dr. Vogel infers from his experiments that he has thus afforded proof that the optical absorptive powers of the admixed substance play an important part in determining the sensibility of photographic plates, enabling them to record an impression within an area not previously supposed to be capable of true chemical activity.†

Such is the important result at which Dr. Vogel has

\* Read before the Photographic Society of London.  
† See PHOTOGRAPHIC NEWS, Dec. 1. 61, 1873, p. 569.

arrived; and his deductions are at all times entitled to be received with the greatest consideration and respect; but they have already been subject to criticism in America, where Mr. Carey Lea, in describing his own experiments, does not hesitate to throw considerable doubt upon the reception of this provisional hypothesis. As a contribution towards the further discussion of this question, I beg leave to relate the particulars of some experiments recently made by myself, which tend to support the objections urged by Mr. Lea.

1. A bromide-of-silver emulsion plate was washed with water, and then coated with an aqueous solution of soluble aurine (coralline). The plate was allowed to dry, and then exposed to diffused daylight for twenty minutes under a double layer of ordinary non-actinic orange glass (such as I have often used in the windows of my collodion operating room, and which freely admits rays of the refrangibility of those in the neighbourhood of the fixed line D). A slip of wood was placed diagonally across the holder, so as to cast a shadow in the event of chemically active rays operating upon the plate. On treating with an iron developer there was no apparent difference observed, and *no image* shown upon the plate.

2. A similar experiment, made with a bromized plate washed with aniline green, and exposed under the same conditions, gave no image.

3. Another plate, treated with the aniline green, was thoroughly dried before exposure, with no different result. This time the exposure was prolonged for half an hour on a bright sunny afternoon, and the attempted development pushed to the point of staining the plate.

4. A sheet of sensitized chloride paper, having both ammonio-nitrate of silver and ammoniacal solution of aurine on its surface, was not found to be affected under the orange glass in the space of an hour. Having used upon several occasions an alcoholic solution of aurine mixed with shellac varnish as a perfectly successful adiacinic medium, it seems impossible to believe that the use of this coloured material should confer a special sensitiveness upon silver preparations placed beneath it without such effects having been previously observed in practice.

As yet I have had no opportunity of working with salicine in the new direction proposed by Mr. Carey Lea; but with regard to the main point at issue, I feel disposed to endorse the statement made by the eminent American author in the concluding paragraph of his paper (*British Journal*, March 13th, 1874, page 121):—"Whilst fully appreciating the interest which attaches to Dr. Vogel's investigation, and his reliability as a practical experimentalist, I cannot help concluding, from my own results, that there exists no law connecting the colour of a substance placed in contact with a sensitive body and the increased or diminished sensitiveness imparted to that body as respects particular rays of light."

The subject of the tinting of films has lately attracted much attention on the part of Mr. Henry Cooper, Mr. Russell Manners Gordon, and Col. H. Stuart Wortley, and a few other new observations, bearing upon the use of colouring materials on sensitive surfaces, have been elicited in the course of this inquiry; but the results are not yet sufficiently elaborated to enable me to include them in this communication.

## ON THE COLLODIO-CHLORIDE PROCESS.

BY GEORGE HOOPER.\*

It is nearly ten years since this society was put into possession of one of the most beautiful and perfect processes connected with our charming art. The principle of holding chloride of silver in suspension in collodion, and thus making a sensitive emulsion, was the invention of our esteemed and active member, Mr. Wharton Simpson. The process was given unfettered, caused

considerable excitement at the time, was frequently designated the chief discovery in the art in the year 1865, produced results that charmed all who saw them, had various applications, and yet has only proved a commercial success in the hands of a small minority. How this should happen is difficult to explain. Some consider that its permanency is doubtful; yet some prints on the table have been done for years, undergone no change whatever, and certainly, as regards permanency, the process will compare most favourably with anything produced upon an albumenized surface. Then others exclaim, "'Tis too troublesome; it is quite impracticable to work the process commercially;" and yet these very gentlemen have never set their brains to work to see whether it cannot be made less troublesome. Is a beautiful process to be condemned because prints have a tendency to roll up when toned? Others think the process slow; but this is a decided error, as it may be reckoned about three times as quick as printing upon ordinary albumenized paper. Others think it very difficult to get a certain tone they desire; but this is really a very easy matter, and quite as much under the control of the operator as the ordinary silver-paper process; and far greater brilliancy, richness, and roundness, or contrast, is obtainable, as well as the print being more upon the surface, and contained in a film of such a structureless nature as to add greatly to the general effect when finished.

All that has been said thus far alludes to the use of the collodio-chloride process upon paper; but when we consider its useful applicability upon glass and various other substances, it is then we cannot praise it too highly. Whether for printing transparencies by contact printing for ornamental purposes upon opal glass, pot metal, ground glass, earthenware, &c., or for any transfer process, in all these directions the collodio-chloride process has unquestionable advantages, and only requires a fair trial to hold a most favourable position when compared with any other known process. But we will return to the discussion of the process upon paper. The cartes handed round for your inspection and criticism are printed upon Herr Obernetter's paper, kindly forwarded to me by Mr. George Bruce, of Dunse. They were my first trials upon this paper, only printed last week, and were toned and fixed in the same baths I use for my regular work; that is, an ordinary acetate of soda toning bath, strength thirty grains of acetate to one grain of gold, and fixed for five minutes in hyposulphite of soda of the usual strength—namely, one part soda to five or six parts water. The prints are first thoroughly washed in two or three waters, and then toned. Any desired tint is easily obtained; they go back very little in fixing, but when dried look more toned than whilst wet. They require several washings before being mounted, but not so much as albumenized prints; and I have found it best to cut the prints whilst still wet, and mount them in the damp state. Before leaving this part of the subject I would add that although the prints just referred to have been toned in an ordinary acetate of soda bath, yet I am informed by Mr. George Bruce and others that they would have been of a still better colour had I tried the sulphocyanide of ammonium bath; and I am convinced such is the case. The rolling up of the prints is certainly a drawback to the process, but not an insurmountable difficulty. The collodio-chloride paper of Herr Obernetter is very good and trustworthy, but has one fault, and that is, it prints too rapidly, or rather the shadows become bronzed before all the beauties of the negative are fully printed out. This is so much the case that an over-exposed and slightly veiled negative is really more suitable than one of good qualities. Greater contrast, brilliancy, richness, and roundness of effect are its favourable qualifications, as well as greater rapidity. I have also received a sample of collodio-chloride emulsion from Messrs. Mawson and Swan, of Newcastle, which is very excellent, though I think it might be made more

\* Read before the Photographic Society of London.

sensitive. In this (its original) form it is very useful, and with slight modifications in its composition might prove available for printing enlarged transparencies in the camera, and produce far more pleasing pictures than any other emulsion process. Perhaps some adept in the art will give it a fair trial, and report at a future meeting. For printing transparencies by contact the emulsion referred to is everything that can be desired. Some specimens on the table, kindly lent for the occasion, have been executed nearly ten years, and not undergone any change, although no particular care has been taken of them. This and many other testimonies all go to speak well of its permanence; and when we take all these advantages into due consideration, and remember that this is a process that has never been patiently and systematically worked out, is it not a question whether such should not be done, so that an easy, certain, and permanent process may be perfected?

Many useful and valuable hints were enunciated at the time of its discovery: and although I have been careful in this short paper to avoid going into the chemical composition of this emulsion, yet I may add that some experimentalists have found great advantages by using "carbonate of silver" instead of "chloride of silver," and others found advantage by adding citric acid in varying proportions. All these and many other suggestions of an important nature should be duly weighed, and, if practicable, aid in perfecting a process which could be used for printing direct in the camera, and with considerable rapidity. The collodio-chloride process upon glass, by development, has never received the attention it deserved at the hands of our clever experimentalists. In conclusion, I trust the few words written, and the prints handed round, will encourage some of our members to give the subject full investigation, and see whether a permanent process surpassing in beauty albumenized prints cannot be perfected, and ultimately become universally adopted, on account of its greater advantages, as well as its simplicity and rapidity of execution.

ON THE REPRODUCTION OF NEGATIVES BY THE POWDER PROCESS.\*

In accordance with your request I have returned the two negatives you forwarded me, together with eight reproductions from the same. I have taken care not to retouch them in any way, so that you may see that all the defects in the original are shown in the reproductions.

The sensitive compound I have hitherto employed for coating the plates is made up of:—

Dextrine	...	...	...	4 grammes
Ordinary white sugar	...	...	5	"
Bichromate of ammonia	...	...	2	"
Water	...	...	100	"
Glycerine according to the conditions of the atmosphere	...	...	2 to 8	drops

I have just made an improvement in the process, however, by discovering a mixture to supersede the dextrine sugar solution which will keep good for years. I have forwarded you a bottle of this new mixture, as also a small flask of the collodion I employ for stripping the pictures; I also send some of the graphite employed by me, and a dusting brush. With these materials, I am convinced, a result will be obtained at the very first attempt.

A new, well cleaned, patent plate is coated with the sensitive chromium solution, and after the superfluous liquid has been allowed to flow off at one of the corners, the plate is dried in the dark by being placed upon a lithographic stone or metal plate, a period of ten minutes being sufficient for the purpose, with a temperature of 120° to 160° Fahr.

The film being perfectly dry, the plate, still warm, is put under a negative, and printed in the shade for ten or fifteen minutes. As soon as it comes out of the printing frame, the plate is again slightly warmed, the brush is dipped into the graphite, and applied over the surface of the image, which should be just slightly visible. The application of the powder is carried on in a shaded corner of an ordinary room illuminated by daylight. You must not press hardly upon the film, with the brush, but move the same over the surface as lightly as possible; nor will it do to hurry the operation.

In proportion as the film cools, so the image appears. By carefully breathing—or, better still, blowing—upon the film, you will be able to accelerate the process, and when the picture has attained sufficient vigour you brush off the superfluous graphite powder with a clean brush.

A normal collodion is now applied, such as I send, composed of:—

Alcohol	...	...	...	500 parts
Ether	...	...	...	500 "
Pyroxyline	...	...	...	15 to 20 parts

When this film has set and hardened, the margins are cut round with a knife, and the plate put into a porcelain dish of cold water. In three minutes the picture will be free from the glass; and the film may be employed in this position, or reversed with a soft brush, and taken out of the water, adhering either to the same glass plate or to another. A gentle stream of water falling upon the film will remove any chromium salts still remaining in the film, and will also press down the loose film uniformly upon the glass surface; finally, the plate is allowed to dry in a perpendicular position. Further treatment of the plate with varnish follows as a matter of course.

The image upon the collodion film is very thin; but you need be under no apprehension of its tearing whilst in the water, where it may be easily manipulated. I have to do with films of this kind measuring three feet square.

I shall be glad to know if the process finds favour with the Photographic Society of London, and trust that you, or some other member of the society, will make experiments with it.

THE PREPARATION OF DIFFRACTION GRATINGS.

BY LORD RAYLEIGH, F.R.S.\*

In testing gratings I prefer to work in a dark room. The slit is fastened in the window-shutter, outside which is placed the heliostat or *porte-lumière*. As slits are frequently required in optical experiments, and, as usually made, are rather expensive, I may be allowed to mention a very simple method by which serviceable slits may often be obtained. A piece of glass is covered with tinfoil, which must be made to adhere well; I have found a weak shellac-varnish a suitable cement. The alcohol is allowed to evaporate, and the thin layer of shellac softened by heat. In order to make a slit, it is only necessary to lay a straightedge on the tinfoil and draw a line with a sharp knife, afterwards wiping the line of the cut with a rag moistened with alcohol. The width and regularity of the slit may be judged of by holding it close to the eye, and observing the appearance presented by a distant candle. The narrower the aperture, the more dilated (in the direction of the width of the slit) the image will appear. Broader slits may be made by removing the foil between two parallel cuts.

At a distance of twelve feet or more from the shutter are placed the grating and the object-glass of the observing telescope. In making the preliminary adjustments, it is convenient to use a slit so wide that the spectra and the light reflected from the grating can be seen on a screen. By the second, the aspect of the plane of the grating can

\* A communication from Herr J. B. Obernetter, of Munich, to Mr. H. Baden Pritchard, War Department, Woolwich.

\* Concluded from page 245.

be judged of; and when the line of spectra is horizontal, it will be known that the lines of the grating are vertical and parallel to the slit. As object-glass, I am in the habit of using a single lens of about twenty-four inches solar focus. The eye-piece is a high power achromatic, supplied by Mr. Browning, and forms, with the object-glass, a telescope of much higher magnifying power than is ordinarily used in spectroscopes. Without a high power it is impossible to bring out the full value of the grating. In order to obtain the best definition, it is necessary to adjust carefully the aspect of the object-glass; and I find that the best aspect is not always the same. It is possible that the performance of other optical instruments might occasionally be improved if means were provided for a slight alteration in the direction of the optic axis of one of the lenses employed. The grating itself I usually place approximately in the position of minimum deviation.

The copies on worked glass by the ordinary photographic processes, and by the modification of the collodion-chloride last described, rarely fail in definition. With the original (3,000) grating, or with the copies, I can make out nearly, but not quite, all that is shown in Angström's map. With this grating, the third spectrum is generally the most serviceable. When the picked patent plate is employed, there will generally be a proportion whose performance is less satisfactory, though few which would not give very fair results when tested by a low power only. Some cannot be considered inferior to the worked glass—at least when the object-glass is specially adjusted for them. In many cases the definition may be considerably improved by the use of a diaphragm in the form of a *horizontal* slit, so placed that only the central parts of the lines of the grating are operative. In respect of brilliancy, gratings may be more quickly judged of; it is sufficient merely to examine the spectra of a candle placed in a dark room.

The lines themselves are, of course, too close to be seen without a microscope; but their presence may be detected, and even the interval between them measured, without optical aid, by a method not depending on the production of spectra or requiring a knowledge of the wave-length of light. If two photographic copies containing the same number of lines to the inch be placed in contact, film to film, in such a manner that the lines are nearly parallel in the two gratings, a system of parallel bars develops itself, whose direction bisects the external angle between the directions of the original lines, and whose distance increases as the angle of inclination diminishes. The cause of the phenomenon will be readily understood by drawing on paper two sets of equally distant and not too thin bars inclined at a small angle. Where the opaque and transparent parts severally overlap, the obstruction of light is, on the average, less than the double of that due to each set separately,\* and, consequently, these places appear by comparison bright. The interval between the bars is evidently half the long diagonal of the rhombus formed by two pairs of consecutive lines, and is expressed by  $a \cos \frac{1}{2} \theta - \sin \theta$ , or approximately  $a \div \theta$ , where  $a$  is the interval between the primary lines, and  $\theta$  the mutual inclination of the two sets.

When parallelism is very closely approached, the bars become irregular, in consequence of the imperfection of the ruling. This phenomenon might, perhaps, be made useful as a test.

If the planes of the films be not quite parallel, bars parallel to the original lines may appear when the line of intersection of the planes is in the same direction. This arises from a foreshortening of one of the sets, making it equivalent to a grating of a somewhat higher degree of fineness.

When examined under the microscope, the opaque bar on the copy, which corresponds to the shadow of the groove

of the original, is seen to be composite, being not unfrequently traversed along its length by several fine lines of transparency. In one case, where the copy was on common glass, this effect went so far that at certain parts of the grating the periodicity was altered by each line splitting into two, the first spectrum altogether disappearing. In order to make this observation, the eye should be placed at the point where the pure spectra are formed, and be focussed on the grating. The places in question will then appear as irregular dark bands.

The disappearance of the first spectrum is very unusual; but it is common for bands to appear when the eye is placed in the place of the fourth and higher spectra. When the order is high, the bands will not be black, but coloured with light belonging to one of the other spectra. There is no difficulty in understanding how this occurs. In the process of copying, the groove of the original is widened into a bar, whose width depends on the closeness of contact, an element which necessarily varies at different parts of the plate. The dark bands are the locus of points at which the relation of the alternate parts is such as to destroy the spectrum in question.

I have not had an opportunity of trying the method of copying on lines closer than 6,000 to the inch; but I have no doubt that the limit of fineness was not attained. I should expect to find no difficulty with lines 10,000 or 12,000 to the inch; but beyond that point it is possible that the method would fail, or require special precautions, such as the use of extra flat glass, and greater pressure to ensure close contact in the printing. For preliminary experiments I should be inclined to try mica as a support, whose flexibility would facilitate a close contact. I may mention that I have done copies of the 3,000-line grating on sheets of mica, which may be obtained very thin and smooth from the photographic dealers. For more convenient manipulation in the preliminary stages of preparation, the mica should be mounted on a sheet of glass of the same size as itself. A small drop of water interposed will ensure a sufficiently close adhesion.

I have tried to take copies of copies, but with indifferent success, even when the performance of the first was not perceptibly inferior to that of the original.

Gratings may be copied without the aid of photography by simply taking a *cast*. Following Brewster, I have obtained a fair result by allowing filtered gelatine to dry after being poured on the 3,000 Nobert. This method, however, is attended with much more risk to the original, and is, besides, open to other objections, sufficient, I think, to prevent its competing with photography.

### TONING, FIXING, AND WASHING.

BY JAMES BECKETT.

THE following specification describes some mechanical contrivances to aid toning, fixing, and washing:—

"This my said invention has for its object an improved system of treating photographic prints immediately after being taken from the negative, so that the operations of 'washing,' 'toning,' 'fixing,' and 'washing' may be performed in a superior, expeditious, efficient, and economical manner, and be converted into a continuous process.

"These my improvements may be carried out by the use of (say) three small troughs having circular bottoms into which the 'toning,' 'fixing,' and 'washing' fluids are placed. These troughs are formed at their ends with suitable bearings to receive the axle of a small drum or cylinder, which is of a convenient diameter to work round in close proximity but not in contact with the bottom of the trough. The prints, when removed from the printing-frame, I first cut to the required size, and then spread them (picture surface outside) over the cylindrical surface of the revolving drum, where I secure them in position by means of elastic bands, or in

\* The mathematical reader will easily prove this from the law of absorption.

any other suitable way. The cylinder I then place on the bearings of the washing trough, and rotate it so as to bring the outer surface of the pictures in contact with the water, to remove the nitrate of silver from the prints. After having performed this operation and discharged the remaining water, I introduce toning solution into the trough, when I again rotate the cylinder until the prints are toned, after which I withdraw the remains of the toning solution from the trough. I then introduce several changes of fresh water to remove the toning solution from the surface of the prints, and afterwards remove the cylinder, with the prints thereon, to the hypo or fixing solution trough. I again rotate the cylinder so as to pass the surfaces of the prints through the fixing solution for a few minutes, and then remove the cylinder to the water trough to receive its final washing.

"In place of using the cylinder or cylinders for carrying the prints, as hereinbefore described, flat surface plates may be substituted, which plates I provide with india-rubber bands, or their mechanical equivalent, for securing the prints thereto, as before described, by which arrangement the dishes at present used by photographers may be utilized by being substituted for the round-bottom troughs described.

"This principle of surface dipping will be found in practice infinitely superior to the total immersion and saturation from both sides of the paper as at present practised, which is highly detrimental and injurious to the prints, and at the same time causes great waste of the expensive fluids used in the several operations.

"I prefer to form the troughs, cylinders, and flat plates of stoneware, porcelain, glass, or other vitreous material or materials; but wood, metal, or other substances may be used.

"In some cases I prefer to attach the upright bearings on which the cylinder rotates to a base-plate or stand, which is arranged to receive a loose trough having a concave internal or other suitably shaped bottom; and in most cases I prefer to construct the uprights with at least two bearings, so that the cylinder being placed on the upper pair of bearings, it will be above and free from contact with the liquid in the trough, which will be found convenient when the toning or other process is required to be suspended for a time, as will be well understood by all practical photographers.

"Having now fully ascertained and described the nature of this my said invention, and the best means I am acquainted with for carrying the same into practical effect, I wish it to be clearly understood that I do not confine myself to the precise detailed proportions or dimensions of the several parts of the apparatus hereinbefore described and set forth, as these, it will be seen, may be considerably varied without departing from the invention; but what I claim is,—

"1st. The improved system of treating photographic prints substantially in the manner and for the purposes hereinbefore fully described and set forth.

"And lastly, the general construction, form, and arrangement of the several parts of the apparatus, operated substantially as and for the purposes hereinbefore fully described and set forth."

## PREPARING PHOTOGRAPHS FOR COLOURING.

BY ROBERT FAULKNER.

This invention consists, in various modes, of giving a surface to photographs suitable for receiving colour, so as to produce a rich and transparent effect. The specification runs as follows:—

"The object of my invention is to obtain an artistic effect in photographs, whether taken direct, or enlargements, either on plain or albumenized paper, or carbon prints, portraits, landscapes, architectural designs, and other subjects, by obtaining by indentation on different parts of the picture surfaces more or less roughened or granulated, which can take tints with greater richness and variety than can be obtained on the usually smooth and uniform surface.

"One method of effecting this is as follows:—I place a sheet of emery, glass, or pumice paper, or paper otherwise roughened or granulated, or linen, in contact with the picture to be operated on, and subject them to pressure, either by passing them between rollers, or in any press of known construction.

"In effecting this process I prefer to lay the print or other subject with its back to the roughened surface, and on the face of the print to place blotting paper or other yielding material of like character, and then subject the whole to pressure. It is advantageous to damp the print in the first place, so that it more readily takes the impression of the indentations. If it is desirable that

certain portions of the picture should be protected from the roughening action, I either cut or scrape out these parts in the roughened paper, or I place pieces of thin smooth paper, or thin sheet india-rubber, gelatine, or collodion film (which is sometimes called collodion leather), goldbeaters' skin, or other suitable material, on those parts of the picture which are to be protected, and then apply the pressure; or when no part of the picture has been thus protected, the indentations made on any part may be afterwards obliterated by means of a burnisher. By this means the picture acquires a granulated surface which will take colour very readily. This colour may be merely a variety of the colour of the picture itself, or other tints may be used, according to the taste of the artist, either in chalk, water, or oil. For vignettes, particularly, this method gives the background a granulated surface, which can hold colour and present a perfectly stippled effect, and this effect can be heightened according to the taste and judgment of the artist and the requirements of the picture.

"This stippled effect can be varied according to the size and grain of the paper or other substance employed for producing it, and the pressure may be repeated several times if desired. The picture, when finished, may be rolled or pressed to give it smoothness.

"Another method is as follows:—I take fine emery or glass powder, or ground silex, pumice, or other similar powder, or filings of metal, and cover those parts of the picture which are required to be acted upon, and then I subject it to pressure, paper, cardboard, millboard, or sheet metal being placed over the picture before pressure is applied. After pressure the powder is dusted off, and colour can be applied to the granulated surface produced by its impression. In applying the powder very little care is necessary, because should the powder overlap any part not requiring granulation, no injury will result to the picture, the grain being rendered visible only when colour is applied to it; or instead of applying the powder to the face of the picture it may be dusted on the back thereof before the pressure is applied.

"Instead of dusting on the powder it may be made into a paste and laid with the brush over the parts of the picture to be acted upon, and when dry the pressure is applied. By this mode of procedure the surface can be prepared well when powerful effects are desired, and often it is desirable to mix colouring matter with this paste.

"The paste may be made with water, alcohol, ether, benzole or any liquid which will not injure the photograph; but no gummy or otherwise adhesive substance should be used, otherwise the powder could not be removed after the pressure has been applied.

"For some effects it is desirable that the powder should remain on the surface. In such cases I serve the picture with a solution of gelatine or other adhesive substance, and while this is moist I sift the powder over it. When dry the superfluous dust is shaken off. This process is peculiarly applicable to carbon prints when just developed.

"When it is desirable to have a surface presenting greater regularity or a lined effect, engraved plates or rollers, such as are employed for embossing fabrics, may be employed for pressing the picture, and the colour can then be applied to such parts of the lined surface as may be desired. In this case also the parts where a lined effect is not desired may be protected by pieces of thin sheet or film before pressure.

"It will be evident that my before-described invention may also be applied with advantage for preparing the surfaces of water-colour drawings for receiving tints.

"Photographs or prints prepared as above described are thus rendered fit for the reception particularly of dry colours, such as chalks, crayons, pastiles, and the like, or pigments applied in the powdered form. For backgrounds of photographs a mineral grey, either in powder or made up into crayon, will be found especially suitable. When the colour is darker than desirable it may be lightened by rubbing with bread, glass paper, or ink eraser. After colours or shades have been applied the surface may be again indented as above described, either for the purpose of heightening the effect of the tints already applied, or in order to render it susceptible of farther tinting or shading.

"Having thus described the nature of my invention, and the manner in which the same is to be performed, I would have it understood that I make no claim for the production of roughened paper generally on which drawings are to be made; but I claim the methods substantially as herein described of roughening by indentation those parts of the surfaces of photographs and other prints on smooth paper to which it is desired to apply colour or shading."

## YELLOW SPOTS ON PRINTS.

ALL the causes of minute yellow spots in prints have not yet been determined with certainty; but a large number of the sources of this prevalent defect have been traced home with tolerable precision. As an unusual number of complaints of trouble in this direction have come under our attention recently, and in mentioning one or two of the most recently suggested origins of spots, we shall add a very brief resumé of other prevalent causes.

It is scarcely necessary to mention the common source of this trouble, from which careless or inexperienced printers most frequently suffer—imperfect fixation. Fresh hyposulphite solution, not too weak; a temperature of 60° Fahrenheit; and constant moving of the prints, to prevent them from sticking together, are indispensable conditions in fixing; and the absence of any of them always produces risk of imperfect fixation, from which must proceed yellowness generally, and patches or spots of dirty yellowish-brown mottling and defacing the print. Care must be taken that minute air bubbles do not form on the print during fixing, or small yellow spots of imperfect fixation must follow. Thorough washing is, of course, necessary, and clean vessels in which to perform the washing are, of course, well understood conditions of clean and permanent prints. It is rather to the more occult, or unexpected, or unknown, sources of spots to which we here direct a few moments' attention.

One of the most puzzling cases of these minute yellow spots, which deface the print and drive the photographer distracted, came under our attention some time ago. It occurred in the hands of a provincial portraitist, and continued for several months. Every possible or suggested cause was carefully submitted to test, without any result. The gentleman in question, one of the most able, precise, and fastidious amongst high-class photographers, came up to town to consult experts amongst theorists and experienced practitioners alike without result; and at last, when verging upon acute mania, a happy inspiration, or a happy suggestion—we forget which—pointed to the coke fire burnt in the printing room, which might give rise to floating sulphurous particles in the atmosphere. The coke fire was at once banished, and with it disappeared the spots of the character which Lady Macbeth so emphatically objugates.

Another case, of equally obstinate character, more recently came under our attention. Again a careful provincial portraitist was the victim, and every possible source was examined with minute care. After a careful consideration of all the conditions brought under our attention, we came to the conclusion that the probable cause was the dust of hyposulphite of soda in the printing room, and

the latest advice confirmed this conjecture. The cause in question is, we are satisfied, a prolific source of annoyance. Small crystals of hyposulphite are dropped and crushed under foot. Portions of hyposulphite solution are spilled and dried up, and the particles remain on the ground. Even drops of hyposulphite solution falling upon the ground, as the prints are lifted from the fixing bath into the washing dishes, eventually leave traces of the dry salt upon the floor. This in hot weather flies about as dust, either when swept up or when trod upon, and these particles of dust, coming into contact with sensitive paper and with prints, become the sources of countless defects and unnumbered troubles apparently without origin.

The action of the bronze powder used for printing upon the mounting cards has been very distinctly traced, and we have repeatedly pointed it out as a sure and fertile source of yellow spots; but, despite warning, we see that it is still most extensively used. In one case, a jar of chloride of lime open in the printing room was found the cause of spots. In another a few crystals of citric acid crushed under foot, and pervading the atmosphere as dust, caused much trouble during many days. The use of liver of sulphur for reducing the silver in the hyposulphite solution has been found similarly troublesome. Mr. Bovey pointed out that particles of oxide of iron hanging about iron developed negatives was a not unfrequent cause of spots on prints. Common cards, acid paste and gum, and other obvious causes need scarcely be mentioned. At a recent meeting of the French Photographic Society a case was mentioned in which the mounting cards were suspected as the cause of spots; but the same batch of prints and the same cards, taken to another photographer's establishment to mount, gave no such defects, and the defect was eventually traced to excessive moisture in the original photographer's printing room, causing a fungoid growth on the albumenized surface. Packing prints in heaps when only partially dried has been found, in warm weather, to give rise to similar spots from a similar cause. There can be no doubt that occasionally defects in the original paper, or in the albumenized surface, are the origin of spots on the print; but photographers are, as a rule, only too ready to attribute such spots to defects in the paper, whilst, in truth, they are, in many cases, due to preventable causes within their own control. A cause hitherto unfamiliar has recently been pointed out by Mr. Anthony, in the *Photographic Bulletin*, which may be worthy of notice. He says:—"Having had occasion recently to inspect some prints that were covered with minute yellow spots, we discovered that each spot marked the place of a small bubble. Whether these bubbles occurred, as they generally do, from the action of the washing water, or whether they were in the paper before it was silvered, could not be determined; but their appearance indicated the possibility of their having occurred in the albumenizing of the paper. Persons accustomed to albumenizing are aware that a fermentation frequently takes place in prepared albumen, which is indicated by the formation of a profusion of minute bubbles. These are sometimes so minute that they are scarcely perceptible. Is it not possible that the yellow spots so often complained of may owe their origin to this condition of the albumen?"

The cause in question appears to be a very probable one in many cases, but in by far the greater majority the trouble rests with causes really under the control of the photographer, the remedy consisting in special cleanliness of atmosphere, water, dishes, fingers, and everything which can come into contact with the delicate and sensitive surface of the print during its various stages of production.

## WESTON'S PATENT ROTARY BURNISHER.

SOME months ago we called the attention of our readers to an important novelty in the finishing of photographs, whereby a degree of perfection of surface was obtained

beyond all comparison more beautiful than any we had seen produced before. This admirable result was produced by a process of burnishing in place of the ordinary rolling pressure which it had been the custom to apply. This valuable and successful modification of the ordinary method of securing a fine surface was due to Mr. Weston, an amateur photographer in the United States, to whose fecund ingenuity in invention the Patent Office in the States, we understand, bears frequent witness. The manufacturer of the burnisher—Mr. J. P. Bass, Mayor of Bangor, Maine—has recently visited this county, and to him we were indebted for various interesting details as to Mr. Weston's invention, and the sight of some very admirable examples of photography by high-class photographers in America, amongst which were some of especial interest and excellence by Mr. Weston himself.

A more extended knowledge of the burnisher, and examination of its results more than confirm our first impressions. It is difficult by merely verbal description to convey an accurate idea of the precise nature and extent of the superiority of the result obtained as compared with rolling pressure merely, a personal examination being necessary to perfect appreciation of the actual gain. A brief consideration of the facts will, however, enable our readers to understand the character of the result obtained. It is not merely polish, or glitter, which, as such, would be an absolutely bad quality in a pictorial surface. It is absolute evenness, the perfection of smoothness, in texture and surface, with such high polish as belongs to a perfectly even and smooth surface. A most glittering surface might be given to an impressed print by varnishing it; but the effect would be vulgar and displeasing. The surface of highly albumenized paper is very bright, but is not smooth and even: it consists of multitudes of little hills and valleys, and the albumen varnish only produces glitter, not a really fine surface. Rolling improves this somewhat by crushing down the little inequalities of surface. But what rolling pressure does to some extent, burnishing does perfectly. This will be apparent on a moment's thought. If the reader will press with his thumb-nail up an unrolled print with all the force he can apply, he will find that he makes but little impression upon the surface; but if, instead of merely pressing, he move his thumb with burnishing pressure, the effect will soon become apparent: and it is this effect which, in an enormously intensified degree, is gained by the burnisher beyond that obtained by ordinary rolling pressure without friction.

The result, should however, be seen in order to appreciate it. Every photographer knows the beauty which a print possesses whilst in the water, before it has been dried, and every photographer has mourned the disappearance of that bloom as the print has dried, the transparent shadows, with minute detail, often becoming a dull, opaque mass, without detail at all. One peculiarity of the burnishing is, that it seems to restore the effect which the print had whilst in the water, and which it lost when dry. It also brings out minute detail admirably, and gives to prints from a good untouched negative, the peculiar modelling and finish seen in prints from a skilfully retouched negative. Some prints of an old coal-heaver, sent to us by Mr. Weston, from what he terms a "raw" negative—the term admirably describes an uncooked, unsophisticated, untouched negative—have all the fine texture of the most perfect retouching. Of course it is in the negative, and when good detail is in the negative no touching can surpass it; but even when in the negative, it is, alas, often unseen in the print, until enamelling, rolling, or, best of all, burnishing, bring all out in the print which exists in the negative. All metropolitan photographers can easily judge for themselves, as Mr. Rouch, who has become agent for Loudon, has one of the burnishers fitted up for use, and will be happy to show its working and result to all interested.

## FRENCH CORRESPONDENCE.

### PHOTOGRAPHIC POISONS AND THEIR REMEDIES—PHOTOGRAPHIC EXHIBITION.

ON more than one occasion the photographic journals have recorded accidents, more or less grave, resulting from poison, fire, explosions, &c., which have taken place in the studios of photographers. All who know anything of photographic matters are aware that those who follow the profession are often attacked by affections contracted in their daily work; the greater part of those who occupy themselves with the art are compelled to live in an atmosphere impregnated with noxious vapours, and to work with chemicals capable of exerting a baneful influence upon their health. Many of my colleagues, and I myself, have repeatedly addressed our readers on the subject of precautions to be taken, and whenever it has been possible we have made known the means of combating the dangerous influences in question. A medical man, who is connected with a great many operating photographers, and who is consequently in a position to furnish much valuable advice, has now come forward to aid us after an experience of several years. Dr. Henri Napias, the medical attendant of the Photographic Benevolent Society of France, has just sent me, for insertion in my journal, a communication entitled "Remarks upon the General Health of Photographers," and I do not think that a few extracts from this document will be unwelcome to your readers.

The first point upon which the author insists most energetically is to the effect that those who live in an atmosphere charged with ethereal vapour should restrict to a minimum the use of alcoholic drinks. Any alcohol absorbed increases the action of the ether that is breathed, and thus injurious effects are brought about which would not otherwise have existed. Walking in the open air is one of the best means of throwing out the ether from one's system, and the taking of seltzer or soda water, or lemonade, or other acid drink, assists also in neutralising its effect. Instead of taking vermouth, or especially absinthe, it is much better to drink, before breakfast or before supper, a small glass of quinine wine, which will have the double effect of neutralising, in some degree, the effects of the ethereal vapour, and improving the appetite and favouring digestion. In any case, when a photographer suffers much from headache—a malady, unfortunately, rather prevalent—it is recommended that a few drops of ammonia and a few drops of vinegar dropped into a glass of sugar and water, be taken.

Among the chemical products which photographers so often employ, the most dangerous are certainly cyanide of potassium, nitrate of silver, bichromate of potash, and the bichloride of mercury. Dr. Napias desires photographers to renounce altogether the employment of cyanide of potassium as a fixing agent, and especially as a means of removing stains of silver from the hands. Photographic operators who have to do with this dangerous substance often have their hands chapped during the winter, and they are then, of course, very liable to be poisoned, if not actually killed, by the application of this virulent compound.

The first symptoms of poisoning, either by the absorption of cyanide through the skin, or taking it inwardly, are pains in the heart and head, a feeling of numbness and sleepiness, and a painful difficulty in breathing, which becomes irregular and interrupted by profound sighs. If the poisoning is in a strong degree, and has penetrated the system through the stomach, the mouth is bitter, the throat and palate are burning, sickness and diarrhoea set in, together with abundant salivation; the pulse becomes insensible, the eyesight is troubled, the pupils dilate, and the eyes appear to grow bigger, while the body is bathed in a cold perspiration. In serious cases a general prostration is manifested, interrupted by convulsions; paralysis succeeds, and death takes place in a syncope.

All these phenomena succeed each other so rapidly that there is scarcely time to observe them and cope with them. In the case of a cure, the bad effects of the poisoning continue for some time, and the patient suffers long from nervous respiration, &c., and sometimes even is smitten with paralysis of certain muscles. As soon as any ill effects are observed from poisoning with cyanide, the wound should in the first place be washed with water saturated with chlorine at the ordinary temperature, and the patient should take two or three grammes of the same upon a lump of sugar. He should be put to bed, well covered up, and hot water bottles placed at his feet and along the body; then the apartment should be freely opened, for fresh air is indispensable under the circumstances. As soon as possible the patient should have a cup of tea or coffee with ten drops of laudanum and one or two dessert spoonfuls of rum or brandy, but on no account kirschwasser. A drink of this kind is administered three or four times at an interval of a quarter or half an hour. If the symptoms continue to be of a grave nature, besides the treatment above indicated, the patient should frequently be allowed to breathe chlorine water, and every five minutes he should be given a teaspoonful of the following compound:—

Chlorine water ... ..	5 grammes
Chlorhydrate of ammonia ...	2 "
Water sweetened with sugar ...	250 "

As soon as the patient shows signs of rallying, the laudanum in the tea may be dispensed with, and the drink is given every half hour instead of every quarter. If no chlorine water should be at hand, the patient should be permitted to breathe ammonia vapour, and fifteen or twenty drops of ammonia liquid should be administered in a glass of sweetened water. Dr. Napier thinks that in all studios there should be a supply of chlorine water and laudanum.

Nitrate of silver, which attacks and blackens the cuticle, is not really dangerous, except in the event of its being swallowed. In this case chloride of sodium, or common salt, is an excellent remedy. A glass of water containing a good pinch of salt in solution will act as a capital antidote.

Bichromate of potash, the use of which is becoming every day more general, has also its dangers. It brings out an eruption upon the skin which may lead to the formation of pustules, or even ulcers, which are very difficult indeed of removal. The fine powder from this salt, mixed with the atmospheric air, and breathed by workmen, brings about a chronic cold in the head, and leads to a fistula attack of the nostrils, which eats away the diaphragm in the nose. Such an accident is, of course, only to be feared in the case of those occupied in the manufacture of this salt. With photographers the harm would, doubtless, never go beyond a chronic cold and inflammation of the eyes; and such things as these may be avoided by washing thoroughly the hands, face, eyes, mouth, and nostrils, every time one has been working with bichromate of potash.

Taken inwardly, this salt acts like a virulent poison, and, in the event of anyone swallowing it, the arrival of a doctor should not be waited for, but a dose of lime-water mixed with milk or albumen should be at once administered. At the same time the arms and legs of the patient are well rubbed with a mixture of five grammes of ammonia and one hundred grammes of alcohol.

Bichloride of mercury, placed in contact with a healthy skin, produces abnormal salivation, and swelling and ulceration of the gums. If the cuticle happens to be broken, a sort of local gangrene is produced. In both these cases chlorate of potash, dissolved in lotions, should be placed to the wound; or, in the case of the throat, a solution should be gargled. If this poisonous substance has been swallowed, then the white of an egg, put into sugared water or milk, must be administered. Iron filings or zinc filings in honey may also be taken.

The Photographic Exhibition organised by the French Photographic Society has just been opened at the Palais de l'Industrie. It is the first since the war, and it is also unquestionably the most interesting that the public have yet had the opportunity of visiting. So far as we ourselves are concerned, we visited the gathering with very great pleasure. The collection of pictures clearly demonstrates how actively everyone has set to work after the misfortunes that overtook this unfortunate country a few years ago, and how quickly they have again taken up the march of progress. Everything in the exhibition is worthy to be examined: there are new processes, ingenious improvements, and clever applications of the art to be seen. Without entering to-day into a detailed examination of what can be seen in the galleries, I may mention that the methods of helio-engraving, photo-lithography, and mechanical prints in greasy ink are represented in a marvellous manner by MM. Rousselon, (MM. Goupil et Cie), Geymet, Thiel aimé, &c. There are some fine enlargements obtained by the new method of M. Lambert, and M. Leon Vidal has sent some views from nature, reproductions of paintings and polychromic portraits, which show the practical progress which the method has made during the past four months, and which leaves no doubt of the future reserved to it. Finally, among that which might be termed fancy work, deserves to be mentioned the portraits executed by M. Puttemans, by means of his so-called Neoleo-painting, of which I spoke in one of my recent letters, and thanks to which all photographers may nowadays pass for artists in oil painting.

It is to be regretted that the photographers from England are so few at the present exhibition, but it must be conceded that those who are present have maintained their position in the foremost rank. ERNEST LACAN.

## AMERICAN CORRESPONDENCE.

### PERMANENT SENSITIVE PAPER

*Permanent Sensitive Paper.*—Photographers have not ceased to search for this great desideratum. At a meeting of the Boston Photographic Association, which I attended a short time ago, Mr. C. F. Richardson exhibited some very rich and brilliant prints, which he had made by a method of his own on paper which had been sensitized for some days; but as he gave his formula and remarks in the form of a paper, I add them here in order that your readers may have the full benefit of them:—

“This subject has been much discussed for the past two or three years, from which its importance may be inferred. But the advantages of a paper which will remain sensitive and white for some weeks before printing, and for some days between printing and toning, are too evident to need a recital. I think it is generally admitted that no process has yet been published by which results equal to those on fresh paper can be obtained; and before giving my method of working, I will briefly review some of those which have been published, and state some of the objections to them. Some of these objections I have learned from actual trial, and others from the published statements of others.

“One of the first methods proposed was by the addition of citric, tartaric, or oxalic acid to the sensitizing solution. Citric acid appears to be the most powerful agent for the purpose. But although paper prepared in this way preserves its whiteness for a long time, I am convinced by numerous trials that as good prints cannot be made on it as by the usual process. The prints, whether the paper be fumed or not, are of an unpleasant foxy red, and although they can be toned to dark tints, they have a peculiar mealy colour, difficult to describe, and as difficult to like.

“Another method consisted in partially washing away the free nitrate of silver after sensitizing, and supplying its place by submitting the paper to strong fuming during the printing. But besides the inconveniences of this, it was admitted by many of those who advocated this method that there were difficulties in the way of producing first-class prints, and the process has certainly never come into general use.

“About a year ago Mr. Hopkins republished a process which had been proposed some years previously, and which consisted in

packing the paper, when nearly dry, between sheets of blotting paper which had been previously soaked in a solution of carbonate of soda and dried. This preserves the paper white for a considerable time, some which I have under trial being two months old, with slight discolouration, but on the second day after sensitizing the prints were flat and poor.

"On the 3rd of May, 1872, Mr. J. M. Turnbull published in the PHOTOGRAPHIC NEWS a method which consisted in floating the paper, when partially dry, on a bath of citric acid. I tried this, and although I did not succeed with it, the prints seeming to need more silver, you will see that I am indebted to Mr. Turnbull for a valuable hint.

"Two evils result from keeping ordinary sensitive paper, which appear to be independent in their nature, although springing from the same cause, viz., the combination of the free nitrate of silver with the sizing of the paper: first, the paper discolours; second, it prints flat and mealy. In any successful keeping process, it is necessary to overcome both these defects, and although there are many ways of preserving the colour of the paper, it does not seem so easy to maintain vigour.

"The process which I shall now give you is no longer experimental, but one by which I have done all my printing for a year and a half, and which two others have used from four to six months with success. Some members now in the room have also tried samples of the paper, and can speak as to the results.

"Supposing that you are using a 40-grain bath, slightly alkaline, prepare the following, which we will call No. 2:—

Nitrate of silver ... ..	1 ounce
Nitrate of ammonia ... ..	1 "
Loaf sugar ... ..	32 grains
Citric acid ... ..	160 "
C. P. nitric acid ... ..	½ drop
Water ... ..	16 ounces

Filter, and place in a tray beside your usual bath, which we will call No. 1. Float your paper from two to three minutes on No. 1, drain well, and place directly on No. 2. Leave it until a second sheet is ready to remove from No. 1; then hang the first up to dry. Proceed in the same manner till you have sufficient to last a week or more. When dry, smooth it out face downwards on a sheet of tissue-paper, and roll it back inwards, and in half an hour it will lay flat in your drawer.

"This paper will now keep two or three weeks in cool weather, and when required for use is fumed with strong ammonia for one hour. After fuming it will not keep so long, but may be relied on for a week at least. Print about the usual depth, and the prints will keep white before toning as long as the fumed paper.

"The paper, being acid, would fail to tone in most baths without some preparation for it; therefore, add to the first water in which the prints are washed before toning saturated solution of bicarbonate of soda, at the rate of about an ounce to a third of a pailful of water. Leave them in this for ten minutes; then give them one or two changes of simple water, and tone and fix as usual, taking care not to overtone. I use the acetate of soda bath, but I have no doubt any good bath will work equally well. I have used different brands of paper with essentially the same results. Should you wish to tone quicker, use more soda.

"Like most acid sensitizing solutions, No. 2 discolours after a time, when it may be necessary to use kaolin to decolorize it. As the sheet is wet when laid on No. 2, but little of this is used up, making the process an economical one. No. 2 improves greatly with use.

"Should a slight scummy deposit show on the paper when dry, it may be disregarded, as it dissolves in the fixing bath; but it may be entirely prevented by the addition of a few drops of nitric acid to No. 2. This deposit is citrate of silver, formed by the alkaline action of the first bath with the citric acid of the second. The amount of nitric acid given in the formula will probably entirely prevent its formation unless No. 1 is too alkaline. As the acid in No. 2 is being constantly neutralized by the alkaline solution on the paper, a few grains of citric acid should be added occasionally if the paper does not keep sufficiently well.

"This paper still did not keep as well as I wished, and it occurred to me that a combination of this method with the carbonate of soda paper might be an improvement. I accordingly packed some in that paper, and I have here a print made on Tuesday, March 31st, from a sheet which bears date February 18th, and was therefore six weeks old. It works as well as if only a week old, and shows as yet no sign of discolouring. This was so

satisfactory that I have for some time practised this addition using common heavy printing paper for the soda.

"Although I cannot, of course, say that there is no other successful method of keeping paper, yet I think a careful consideration of the manipulation employed will show good chemical reasons for the success of this process. When a sheet of salted paper is floated on a solution of nitrate of silver, it is well known that the character of the chloride of silver formed differs greatly, according as the solution is alkaline or acid, and considered independently from the condition of the soluble silver remaining upon the paper. This is also seen in the collodion process, for if a plate be excited in an alkaline bath, which is afterwards washed away, and the plate developed in the usual manner, it will show the effect of the alkaline bath by fogging. On the contrary, a plate may be excited in an acid solution, covered with an alkaline preservative, and afterwards developed with perfect clearness.

"We all remember the change in the character of our albumen prints upon the introduction of the alkaline silver solution and ammonia fuming, the strength of silver and time of floating being greatly reduced. Paper floated upon an alkaline solution furnishes the chloride of silver in the best condition for printing, both as regards sensitiveness and vigour, but also, and by virtue of these qualities, it discolours and spoils sooner. If the free nitrate of silver be entirely washed away from such a paper, it will keep some time, but at the expense of both sensibility and vigour. I therefore come to the conclusion that in the method which I propose the chloride of silver retains the peculiar properties conferred by an alkaline formation, while the acid of the second solution prevents the free nitrate from acting on the sizing of the paper to its discolouration, and also forms a small quantity of citrate of silver, which still further helps in the production of a vigorous print. The only purpose of the nitrate of silver in the second bath is to retain a sufficient amount upon the paper to produce a vigorous impression.

"Although I cannot claim to have completely exhausted the subject, the above theory is sustained by the fact that I have so far been unable, although I have made many trials to that end, to combine the ingredients of these two solutions, or the solutions themselves, in one bath that would produce the same results. I hope this process may receive a fair trial at your hands, as I am confident that you may by its use secure all the advantages of a practically permanent sensitized paper, without the sacrifice of any quality of good printing."

EDWARD L. WILSON.

## ON THE INFLUENCE OF COLOURED BODIES ON THE ACTIVITY OF DIFFERENT RAYS.

BY PROF. H. VOGEL.

I FIND in the *British Journal*, May 15th, an answer to my notice, in the issue of March 27th, page 154, of the PHOTOGRAPHIC NEWS, in relation to the action of colours on the sensitiveness of silver salts. I made the objection to Mr. Lea's experiments that he did not work with a true spectrum (*i. e.*, with pure colours), but only with the impure colours of glass strips or pigmented varnishes. I gave striking instances that the action of such artificial colours is, in many cases, quite different from the action of the pure colours of the spectrum, and that, therefore, Mr. Lea's experiments with impure colours neither contradict nor confirm any of the facts I have observed with the pure colours of the spectrum.

Mr. Lea now contends that I, in one case, employed a coloured glass strip (a yellow one). That is so: I used in a single experiment such a glass strip, but not for proving the action of pure colours, but for quite a different purpose; and I have not deduced from this experiment with impure colours conclusions on the action of pure colours, as Mr. Lea does. Working with impure colours in spectro-photographical researches is exactly of the same effect as working with impure chemicals in a chemical analysis. That is an assertion I need not prove to any who have worked with the spectrum.

I was not less surprised by a remark Mr. Lea makes to defend his experiments. He says: "Moreover, in a considerable number of cases any possible objection of the kind was obviated by the use of the same pigment to

colour the glass as to mix with the silver bromide. Well, mix, for instance, red coralline (which absorbs the yellow rays) with bromide of silver, and you will observe a strong impression of the yellow rays in the spectrum; but now expose the same coloured bromide under a glass strip coloured with the same pigment, and the result is easy to foretell: the yellow rays are absorbed by the glass strip before they could reach the bromide of silver; and certainly you cannot get the action of yellow rays on the bromide, because there are no more yellow rays in the light, which have passed through the glass strip. If Mr. Lea cut off in this manner the coloured rays, wholly or partially, which, according to my observations, act on the same coloured bromide, he can, indeed, never observe this action.

In the Proceedings of Societies, p. 237 of the NEWS, I read, also, some remarks from Messrs. Spiller and Stillman, who worked with coloured films, but without the success I have had. I am not astonished at this fact. In my first experiments in this direction I had no success; but I continued, because I was convinced that my theory of the matter must be true, and that I needed only to find out the practical conditions under which the principles work. If Mr. Spiller would publish his *modus operandi*, I could easily find out the reason of his non-success. The practical conditions of success will be published in *Poggendorff's Annalen*.

### PHOTOGRAPHY IN BOHEMIA.

BY G. STRAUBE.

ONCE more, after an absence of more than twenty years, have I again visited Germany and Austria, and settled down for a time in the old historical and beautiful city of Prag, in Bohemia. But the old love for the art of photography is still so strong as not to be able to resist the longing to see the various photographic places, to scrape up acquaintances, and have a chat on various subjects.

I have been struck by the beauty of portraiture throughout Germany, and suffered no disappointment after what I had been used to, and left now behind me, in old England. Splendid works of art did I see in Hamburg, Berlin, Dresden, Vienna, &c., and I am bound to express my opinion that, on the whole, the art of photography here has attained a higher standard of excellence than I have found in old England. It would do many photographers and amateurs a great deal of good if they would take a trip to the Continent, which, owing to the remarkably low price by railways and steamers, is not expensive for travelling, and, from the beauty of scenery, and what is to be seen in photography, would greatly increase their stock of knowledge.

I had the pleasure of calling upon many of the first-class photographers at the various cities through which I passed, and am pleased to be able to state that in every instance I received a hearty welcome, and all the information I required, so far as was possible, was gladly given me. What struck me most was the freedom from selfishness, secrecy, or exclusive police. Here at Prag I have made the acquaintance of most all photographers, but especially that of Herr Heinrich Eckers, a hard-working man, whose name has a good repute through Germany and Austria as one who labours, for the love of art, to explore the hidden riches of this beautiful art; and numerous are the prizes, medals, and testimonials in acknowledgment of his talents. Not only is his work very good in portraiture, but also in the taking of landscapes. And I may also mention here that he is the only one in the city of the Protestant faith, and, in spite of that, has almost all the work in the cloisters and nunneries to do. I have been so fortunate as to accompany him to a few of these, and I will, at some other time, write a chapter about photography amongst monks and nuns, if your readers would like to

know something about these fair creatures. But I enter now upon nothing but gossip, which is not in accordance with your valuable paper.

I will, before I close, say but a few words more about Herr H. Ecker, which, by right, should have been said at first: that he is one of the pioneers in the field of photolithography and photo-collography, and works a process entirely his own with great success. It much resembles the Albert-type, and is very simple. A proof of his process being good is shown by Herr Albert coming here last year to pay Herr Ecker a visit, and express his delight. As Herr H. Ecker makes no secret of his process, and feels a delight for others to profit by it, he requested me, if I would take the trouble, to make known to the world all his various processes, an offer of which I will avail myself, so far as may be possible for me to do. But I would draw your readers' attention to a book at present in the exhibition at Kensington. It is a reproduction, by photo-lithography, of an old valuable Latin Codex, by H. Ecker. This same volume was last summer at the exhibition at Vienna, and gained him the exhibition prize, and also, from the Emperor of Austria, the Cross of Merit (*Verdens Krentz*). This reproduction is so very good, and in all its details so sharp, that it is to be regretted that the paper had not been toned to give it the appearance of age, when it would have been difficult to decide between original and copy. The original is of the fourteenth century, and, of course, written. It is highly valued and praised, and is one of the best manuscripts amongst the treasures of the St. Veit Cathedral at Prag.

Should ever any of your readers be willing to come to Prag, I should be most happy, for old England's sake, to make him welcome, and show him our lions. But more in my next.

### ON SENSITIVENESS.\*

ON the first glance at this heading some of my readers may be in doubt as to what it refers; and so, to prevent misunderstandings, I may as well state that nothing personal is meant by it, although many of our artist brethren possess very often a degree of sensitiveness for praise or blame which I should like to see transferred to thin collodions. But of this over-sensitiveness on their part I do not desire to speak just now.

Occasionally we have a collodion praised as something extraordinarily good, which, if tested by several photographers practically, is the subject of different verdicts. One is enthusiastic over its properties, another is cold, and the third gives no opinion one way or another. Contradictory judgments of this kind may result even when the exalted collodion really possesses good qualities. I myself once received a good sample of collodion which I shared with a colleague, and this gentleman did not by any means agree with me in the super-excellence of the compound. "It is good enough," he said, "but my own formula yields a material quite as sensitive." On examining into the matter I found that he was not altogether wrong in his view. The manipulation of different operators varies a great deal. Many are in the habit of exposing for but a few seconds in portraiture photography, whilst others again, even with a good light, give a period of from twenty to thirty seconds. To the latter class belonged my friend, and he proved to me that, with his mode of working, the collodion I had given him did not act any more quickly than that prepared by himself. We then exchanged collodions, and I tried his material, giving short exposures, as was my wont, and then I found that his collodion was considerably behind the newer product. To find out where the fault existed, I made a few pictures with different exposures with the two preparations, and then I discovered that, in fact, my collodion required ten seconds less exposure than the other;

\* *Photographische Notizen*.

but that when, with both materials, an exposure of thirty seconds was given, then the other collodion caught up to mine. Two plates which had received long exposures exhibited little difference in the nature of their film; although the two collodions, if exposed for a brief time only, were widely different.

At the same time the character of the pictures in the two plates was differently marked. In my collodion the lights were very strong, almost over-exposed, while in the other they were more transparent and more finely graduated. The last point is of importance. How often do we complain that the white linen and white garments appear as a patch in the picture! According to my view, details in the lights are just as important as details in the shadows, and a collodion which shows fine gradations in the lights will exhibit finer half tones than one which renders high lights too densely.

But it may be said that if sensitiveness for the shadows is wanting, then the picture becomes hard. This is quite right; but then I assert that with a not insensitive, but less sensitive collodion, harmonious pictures may still be produced when the shadows in nature are lighted up as much as possible during exposure. A hundred instances in practice prove this. I could cite many a skilful photographer whose collodion is not of a most sensitive nature, and who nevertheless produces excellent portraits with it. Collodions which show the greatest sensitiveness give the high lights too dense, as a rule; they are much to be recommended when working in a dull light, because in this case the high lights are usually flat enough. If, however, a strong source of light is at hand, and especially bright objects to be depicted, then a less sensitive collodion is to be preferred, for it gives more details in the lights. Only, care must be taken that the shadows are properly lighted up. Reutlinger, of Paris, who at the Vienna Exhibition showed some very beautiful portraits with finely detailed white drapery, works in different lights with different kinds of collodion.

It would be an important matter if manufacturers could produce us a collodion which would be excessively sensitive for the shadows, but not in the same degree sensitive to the high lights. Whether such apparently contradictory qualities could be imparted simultaneously to a collodion is a question. The addition of bromine salts will not advance matters. These act very well as regards sensitiveness for shadows; but if too much is added, then the sensitiveness of the collodion decreases altogether. An increase in the amount of pyroxiline also increases the sensitiveness of a collodion, but, seemingly, in a greater degree for the lights than the shadows.

I would, however, recommend nobody to tamper with a good commercial collodion, for it is seldom that any good comes of it. I know people who are continually altering their receipts, and swear, at every new trial, that the philosopher's stone has been found; and yet, when it comes to taking a good portrait, they invariably fail. It is best to stick to one kind of work where it is a question of business; at any other time one may experiment as often as time and opportunity permit.

Those who desire to modify highly sensitive collodion which gives too dense lights may dilute it with one-eighth or one-tenth its volume of ether. The collodion will then work more slowly, and render the high lights more delicately.

#### ABOUT THE DEVELOPER.

BY DR. H. VOGEL.\*

ABOUT two years ago it was rumoured in Berlin that a young and very skilful photographer was in the habit of employing a developer which did not contain alcohol. The matter was much talked about as quite an exceptional circumstance, and was disbelieved by many. But it is nevertheless a known fact that with freshly prepared silver baths no alcohol is really necessary in the developer, although it

becomes requisite as soon as the silver solution has been used for some time, and has taken up alcohol from the collodion plates dipped into it. The photographer in question, however, found that no alcohol was contained in his bath, for the simple reason that every night the liquid was emptied into a shallow porcelain dish, and the spirit allowed to evaporate. I asked him for the recipe of his developer, and it was as follows:—

Sulphate of iron ... ..	5 parts
Glacial acetic acid ... ..	3 ..
Water ... ..	100 ..

At once I saw the explanation of the circumstance. Alcohol was not included in the formula, it is true, but glacial acetic acid was there, and photographers are not all aware that alcohol and glacial acetic acid exercise in some cases a similar action. If you use an old alcoholic silver bath, and develop a plate from it with a developer containing no alcohol, but one per cent. of glacial acetic acid, the result will be a streaky plate, because the alcoholic film repels a solution containing no spirit; but add two or four per cent. of alcohol to the developing solution, and the defect disappears. And exactly the same result is secured when more glacial acetic acid is added instead of alcohol. From this it follows, therefore, that the action of acetic acid is physically the same as that of alcohol, for it facilitates the flowing of the developer over a film prepared in an old silver bath.

To chemists the circumstance will appear by no means surprising, for alcohol and glacial acetic acid behave in the same manner as regards their repellent action against aqueous fluids. As a rule, it is stated that the acid has the effect of retarding the development and clarifying the developing solution. The latter view is correct, but not the former. A developer may be prepared to which no acid whatever is added, but as much alcohol instead, and it will be found that the same acts quite as slowly as if it contained acid. I have, indeed, often employed a developer which had no acid at all in its composition, but only alcohol, and have obtained good results with it. But this developer I found became turbid on standing, a circumstance that may be avoided by the addition of one-tenth per cent. of sulphuric acid. With such a developer, containing no glacial acetic acid at all, I have worked for years, as also my pupils. Additions to the developer of such substances as sulphate of copper, sugar, &c., which have often been recommended, have no particular value. Sugar acts somewhat as a retarder, such as is desirable in the case of freshly prepared baths and a strong light; but the same effect may be just as readily produced by employing the developer in a more dilute condition.

I cannot forego this opportunity of telling a curious little episode from life concerning the developer. A photographer in Silesia, who is now dead, complained to me of development streaks, and sent me a plate which, truth to tell, was really an awful sight. He stated that he had tried everything he could think of to overcome the difficulty. He had altered the proportion of alcohol and acetic acid, had employed new silver baths, &c., but all without success; and in the developer, therefore, must be the fault, for the streaks only become visible upon its application to the plate. I examined the test plate more carefully, and discovered that the so-called development streaks were observable only in the background. On the outline between the figure and the background they ceased altogether; in the figure, on the floor, &c., there was not a trace of them. There was no doubt in my mind, therefore, that the streaks in question were simply the folds and creases of the background itself. I recommended the photographer to change, not his developer, but his background, and the cure was at once at hand.

A number of photographers employ the developer in intensifying, while others, again, will have nothing to do with it in this capacity. "It produces stains and a mealy

\* *Photographisches Notizen.*

precipitate," they say. I quite agree in this opinion, but would add that both stains and precipitate are to be avoided. Stains or streaks are formed because the silver solution added to the developer has the effect of diluting it, the percentage of alcohol becomes smaller, and the liquid does not flow evenly over the plate. For this reason I employ, for intensifying with iron, a solution of silver which contains as much glacial acetic acid as the developer contains alcohol, or alcohol and acid together. For instance:—

Water	...	...	...	100 parts
Citric acid	...	...	1½ to 2	"
Glacial acetic acid	...	...	2 to 5	"
Nitrate of silver	...	...	2	"

With such an intensifying solution as this, there need be no fear of repulsion by the film. Mealy precipitates are avoided by washing off the intensifier as soon as it becomes turbid. Braun, of Dornach, intensifies with iron. As a matter of course, the iron intensifier is only serviceable where moderate vigour is desired, as in the case of portrait or landscape photography. In this case intensify before washing the plate. If, however, it is a question of a very dense film, as in the case of reproducing drawings and engravings, a pyrogallic or other intensifier must be employed.

### Talk in the Studio.

**OBITUARY.**—Died, at Falmouth, on the 13th instant, Mr. James Siddons, Photographer, formerly of Sheffield.

**HABIT.**—There is nothing that influences us all in every department of life more than habit. Sometimes it is for good, sometimes for evil. It is like one's growth, it comes upon us so imperceptibly that we are scarcely aware of it before it is fixed irrevocably as a part of our being. In many cases acquiring a fixed habit is a great blessing; it enables one to perform a great many of the duties of life with but little effort; habit has made it a sort of second nature. In this direction may be mentioned honesty, promptness, punctuality, truthfulness, perseverance, order, system, &c. Some of these are inborn principles, yet they are all susceptible of improvement or degeneration. In photography habits of cleanliness, order, system, punctuality, and doing none but the best work, are virtues that every one should strive for; but in methods of working and many photographic manipulations habits are a pernicious evil. In coating and developing plates there should be no fixed habit, for the condition of the collodion, the temperature, the bath, the time of exposure, the lighting of the sitter may require change from day to day, and often, in some parts of the process, in every plate that is used. Habit will make a man hold his plate just so, whether his collodion be thick or thin, whether he wants a weak or intense negative. It will make him flow his developer the same without any consideration as to other conditions; it demands that every sitting should be made in the same place under the light, that screens and shades should be arranged in the same manner, that the camera should always be the same height, and that the same position and view of nearly every face should be made. Now there is nothing to be deplored in any man's work more than stereotyped methods or mancrisms, that become so patent that it is not necessary to look for the name on the back of the picture—it appears in the picture to all that are familiar with the work of the individual. Habit in this direction, then, like habits of dissipation, should be carefully guarded against, keeping the mind and hands as elastic and as free to adapt themselves to circumstances as the air we breathe.—*Photographic Times, U.S.*

### To Correspondents.

**OLD B.**—The want of coincidence between the chemical and visual foci used to be a common characteristic of the lenses of the maker in question. You cannot easily have it altered. Your only remedy is to move the lens for just that distance which experience teaches you is necessary. It is doubtful whether any systematic scale could, with advantage, be laid down.

**G. FREDERICK.**—The defect you describe is a very familiar one. You are fortunate never to have met with it before. Your bath from long work, has become over-iodized; that is, it has gradually acquired more iodide from the coated plates than it can hold in solution, and the consequence is, that small crystals of the double iodide and nitrate of silver are thrown down upon the film, which produce pinholes in the negative. There are various remedies. A very simple one consists in adding an equal bulk of fresh un-iodized nitrate of silver solution. Another consists in first pouring the nitrate bath slowly into an equal bulk of distilled water, which will turn it milky; then filter, and afterwards add nitrate of silver to make the proper strength. Or simply add a couple of drops of hydrochloric acid to each pint of silver bath. Read various articles in last volume of NEWS and in the last two or three YEAR-BOOKS on the subject.

**AMATEUR.**—You may use the preservative solution to the end without altering it. 2. They keep well, but how long we have no means of saying. 3. About equal proportions of ether and alcohol when it gets unworkably thick. 4. The condition of the emulsion keeps changing very much. Read Mr. Cooper's articles on keeping and reviving emulsions, in our last three or four YEAR-BOOKS.

**FRED. YOUNG.**—With plates intended for immediate exposure, Mr. Gordon frequently washed off the gum. With plates intended to keep, the gum was always left on the plate. 2. Moderately good washing, but only sufficient to thoroughly soften the gum. 3. Yes; a little, amount proportioned to the rapidity of development.

**F. M. D.**—See article on another page. The yellow spots on the print marked A appear to have been the result of air-bubbles on the print whilst in the fixing bath, causing imperfect fixation. 2. The uneven toning may be due to one of two or three causes. A common cause is the presence of more free nitrate at one end of the print than the other. This would arise from the accumulation of the silver solution at one edge whilst hanging to dry; and the greater proportion of free nitrate would cause toning to go on quicker at that part. Another cause might be the draining of the albumenized paper carrying a thicker coating of the albumen to one edge of the paper, and the excess of albumen would cause the print to be somewhat redder in that portion. There appears in the prints a slight excess of albumen towards one edge as compared with the other.

**R. P. K.**—We have published many formulæ for making paper transparent for colouring at the back, and have no means of knowing the particular one to which you refer. The best plan is to soak the print in hot water first, so as to dissolve out the size, and then it may be made transparent by soaking with gum water; or it may be dried and made transparent by treating either with white wax, or Canada balsam dissolved in turpentine, or many similar preparations. You will no doubt be able to obtain the mislaid copies of our Publisher an application.

**F. H. W. B.**—Your negative reached us in fragments; but we are quite familiar with the defect, which is that commonly known, and often written about, as "matt silver stains." They spring from a combination of causes, but the collodion is the primary cause. It is of the horny, repellent character, which causes the solution to run in irregular, greasy-looking lines, which issue in the worm-like tracks of matt silver. Some want of precision and care in manipulation increases the tendency to this defect. A change in the condition of the collodion is one of the best remedies. Sometimes age will effect this change; sometimes the addition of one or two drops of distilled water to each ounce of the collodion will effect the change. Immerse the plate before it is as much set as usual. Be sure to allow the plate to rest upon pieces of fresh clean blotting-paper in the dark slide, and frequently wash the inner frames to secure perfect cleanliness. Allow no undue lapse of time between the plate first leaving the bath and development. If you read back volumes of the NEWS and YEAR-BOOKS you will find many articles devoted to the subject.

**GUSTAV STRAUBE.**—Many thanks. We shall have pleasure in hearing from you, and hope to write to you soon. Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.  
PRESERVATION OF RELICS BY PHOTOGRAPHY—PHOTO-  
CHROME—POISONS IN THE STUDIO.

*Preservation of Relics by Photography.*—In Mid Germany, in the grand old forest of Thuringia, there has been for some time past a little hut in the vicinity of Ilmenau, which Goethe turned into a summer-house, and oft frequented when desirous of rest and seclusion. The black pine trees, with their shade and fragrant odours, were so dear to Germany's greatest poet, that nearly every summer, for a score of years, he visited the retreat; and here it was, inspired by the quiet beauty and peaceful repose of the scene around, that he wrote his celebrated *Nachlied*, or "Ode to Night." This sweet little poem was scribbled one evening in pencil upon the door of the hut, and while a recognised favourite with his readers, it was held in the highest esteem by the great genius himself. He was never tired of reading over the crude characters as he had pencilled them down upon the plank, and from time to time he would go over them again to render them more legible. By-and-by, when Goethe had ceased to wander about this earth in the flesh, pilgrimages began to be made to the little summer-house upon the *Kickelhahn* hill, which was still supposed to be haunted by the spirit of the gifted being, and the forester of the district was entrusted with the safe keeping of the shrine and its valuable manuscript. Great vigilance had to be exerted to prevent injury being done to the place by relic hunters, and one day the forester came upon a tourist—he was said to be a blonde-haired son of Albion—in the act of sawing out bodily the much-coveted plank with the precious lines inscribed upon it. Every year the trust became a more responsible one, and at last it was resolved to place a frame and glass plate over the relic, and have recourse to the photographer to secure a *fac simile* of the writing and its surroundings, in case of any untoward accident. The aid of the camera was not invoked a moment too soon, for very shortly afterwards a fire occurred in the hut—whether due to accident or design is not known—and in a few hours the little house was a heap of ashes. The photographer's plate, however, had retained an impress of the original, and from the image, thus timely secured, engravings upon metal were at once produced.

*Photochrome.*—A photochrome, or photochromic image, we have come to look upon as meaning a photograph produced in its natural colours, such as those which Becquerel and Niepce de St. Victor were in the habit of securing by means of the violet sub-chloride of silver. The word has also been used by M. Leon Vidal, we believe, for the coloured impressions he produces by superposing several monochromes. It was with no little surprise, therefore, that we came upon a paragraph in the *Paris Figaro*, the other day, which defined the word in quite a novel manner; and as this seems to be the more recent definition, we consider it our bounden duty to make our readers acquainted with the same. Photochrome, according to our Paris contemporary, it seems to us, means more how to make a picture of oneself than anything else, for it is, we are told, "a new pomatum, that renders again to grey hair its primitive colour through the action of light; being, indeed, photography applied to the hair-dresser's art." As nothing is said about toning and fixing the head afterwards, one can hardly understand how the photographer is to be made use of in improving one's locks, or what the *modus operandi* may be. The only plan of proceeding that occurs to us for the moment is, that the grey hair is rendered sensitive to light, and then another head of hair of the desired tint is placed near at hand, and reflected by means of a lens or other means upon the decayed curls, which thus become impressed with the tint of the original. But it is scarcely worth while, perhaps,

to go into the matter very fully, for, after all, the definition given may only be the advertisement of some enthusiastic hairdresser.

*Poisons in the Studio.*—The valuable hints given by M. Ernest Lacan, in our last issue, upon the subject of poisons in photographic studios, and upon the best plans to be pursued in the case of the same getting into the system, cannot be too closely studied by photographers. Dr. Napias has, seemingly, studied the matter very fully, and has given much attention to such of the poisons as, in ordinary manipulation, an operator comes in connection with, and which poison by contact, the solution penetrating through the pores of the skin. At the same time, it behoves one to pay attention to the effects of the substances also when taken internally, either through accident or design; and we would supplement Dr. Napias' valuable observations by a word on the subject of pyrogallic acid. To give some idea of the injurious character of this universally-employed compound, it may be mentioned that its poisonous action upon the stomach and system is not only as deadly as that of cyanide of potassium, but its effects are far more distressing to the sufferer. Cyanide of potassium brings on syncope very speedily, and then an unconscious death; but pyrogallic acid produces most acute pain, and its action is slow and agonising. It acts, indeed, when taken internally, very much in the same way as phosphorus. The amount that will ensure death is calculated to be about a quarter of an ounce. Sixty grains given to a dog caused it to die in a couple of days, while thirty grains brought about the same result in sixty hours. A substance which is to be met with in most photographic studios—certainly in those in which carbon printing is carried on—is, according to M. Personne, an excellent antidote for pyrogallic acid: we mean oil of turpentine.

## M. DUCOS DU HAURON ON HELIOCHROMY.

A SECOND pamphlet has just been issued by M. Louis Ducos du Hauron in continuation of his work published in 1870 upon producing photographs in colour. M. Hauron's method, it may be remembered, is to secure three monochrome prints by means of three negatives of any object, taken respectively through orange, green, and violet glass screens. As all mixed colours are combinations of the three primary colours, red, yellow, and blue, M. Ducos argues that by building up with monochrome images of these three tints, a representation of an object in its normal colours ought to be obtained. He photographs the object, in the first place, through green glass, thus cutting off all rays except those of the same colour as the glass, and of the negative thus secured he makes a copy by the carbon or Woodbury process in red; a second negative is taken through violet glass, and of this an impression in yellow is obtained, and the third negative is taken by the aid of orange glass, and printed in blue pigment. Several obstacles were in the way of working the process, not the least of which was the difficulty of securing an image behind an orange glass, even with a very prolonged exposure; and it is for the purpose of reporting progress that M. Ducos comes before the public again.

He now states that he is enabled to reduce very considerably the duration of pose required for the formation of an image behind red and green glass, to employ for his three negatives an ordinary collodion, and to simplify the manipulations considerably.

He goes on to say, "Before describing my operations, and indicating the formula employed, I hasten to rectify an error in my previous publication of 1869 and 1870, an error into which it was easy to fall, as will soon be seen. It consisted in the assertion that the anti-photogenic colours were incapable of furnishing latent images susceptible of being developed by known agents. This statement is true

in certain cases, but incorrect in others, as a prolonged research has convinced me.

Thus, a collodionized plate, containing either iodide or bromide of silver, exposed moist to red light in the camera, with or without an excess of silver, will yield no image on development, even after an exposure of three hours in the sunshine. A plate of the same kind freed by washing of its excess of nitrate of silver will, on the other hand, after an exposure of two or three hours in the sun, yield an intense image. This is, it will be seen, quite the contrary to what happens in white light, which impresses the salts of silver more rapidly in a wet than in a dry state. Finally, a plate of the same kind exposed to the same red light, if certain materials have been introduced into the collodion—such as resin, for instance—will give an image quite as well wet as dry. When iodide of silver is used with an excess of nitrate, the wet image is more intense than the dry. But one essential condition to be noted is, that the preservation of the image in a wet state, such as I have referred to, must not be obtained by the addition of a hygroscopic substance, such as a mixture of albumen and glycerine. If this method of maintaining the moisture of the film is adopted, it will be insensitive to red light. Another means must be employed, therefore, and this consists in approaching the red glass to the film to within two millimetres, and thus imprison between the two glasses an air saturated with moisture. A second condition, not less important than the rejection of albumen and glycerine, is that of employing only distilled water for washing; for the presence of the slightest trace of salts in the water is sufficient to injure the sensitiveness of the film for red light."

M. Ducos then states that his attention was called to Dr. Vogel's experiments, in which a red colouring matter named coralline was employed in the bromized collodion, rendering the latter as sensitive to yellow as to the indigo rays.

"Struck by this observation of M. Vogel, I was curious to know if bromized collodion coloured with coralline was not capable of furnishing images in red light more quickly than was the case when resin is used. The researches which I conducted with this view proved to me that bromized collodion coloured with coralline, and employed either dry or wet, is much more impressionable by red light than any other collodion. The idea then occurred to me to try iodized collodion coloured with coralline, and the result was a most happy one, for it was found to be much more quickly acted upon by red rays than the bromized collodion. It permits one to produce in the camera with red light, with a doublet lens of medium rapidity, a landscape illuminated by the sun in twenty-five or thirty minutes; the same preparation allows one to take a negative of the same subject with green light in two or three minutes; while with blue light an image is secured either instantaneously, or with an exposure of two or three seconds, according as the tint of the glass is more or less pronounced.

"I have found that, besides this, iodide of silver gives, by means of the green and yellow screens, a translation into black of the different colours, which conforms to the heliochromic theory, and in this respect it is superior to bromide of silver. This last, employed alone, furnishes, with the green glass, a negative in which the red objects are by no means feebly represented, and with the violet a negative in which the yellow objects are, on the contrary, a little too pronounced. This apparent anomaly is the result, evidently, of the bromide of silver being too sensitive to certain rays which enter into the composition of the green and violet glass, and of which the action upon our organ of sight is dominated by the action of other rays of the spectrum. Four parts of iodide and one part of bromide in the collodion succeed very well, and such is the proportion that I recommend."

M. Ducos then goes on to describe the practical carrying out of the operations. He employs a collodion containing four parts of iodide to one of bromide, and to every hundred cubic centimetres of this collodion adds four decigrammes of red coralline, which is soluble in alcohol. Three plates are coated in the ordinary way, and if the wet process is used the coloured glass screen is arranged in front, and almost touching it, so as to prevent the evaporation of the collodion upon the plate. To avoid any danger that might arise from a condensation of moisture upon the sheet of coloured glass, this is coated with normal collodion, so that its surface remains in a wet state. The exposure required for each of the three successive plates must be estimated, as nearly as possible, according to the basis already laid down. The development is conducted, as usual, either with iron or pyrogallic acid, the plate being redipped if a long time has elapsed between exposure and development; and when fixed, the negatives are coated with:

Water ... ..	100 cubic cents.
Albumen ... ..	25 "
Glycerine ... ..	4 "

When dry, the red tint given by the coralline is removed by pouring over alcohol repeatedly, which has the effect, also, of hardening the image by coagulating the albumen. A hard varnish is finally employed.

In photographing by the dry method, resin is added, besides coralline, in the proportion of two or three decigrammes per hundred cubic centimetres. The washing of the plate is conducted with distilled water alone.

To secure the three negatives of perfect sharpness and of the same size, each of the coloured glass screens should be put quite close to the sensitive plate. The interposition of the coloured glass having the effect of changing the focus slightly, this is easily remedied by fitting to the frames serving for focussing, against the polished surface of the glass, a colourless plate of the same thickness as that of the coloured plate which is fitted in the camera or dark slide. Of course all the coloured plates must be of the same thickness. In this way a correct focus of the object is secured.

Care must be taken in choosing the coloured glasses. Coralline-tinted collodion applied to a plate may be employed instead of red glass; and when the wet process is employed a more intense red is desirable than with dry plates. The green plate should show blue and yellow objects with equal definition. If too blue, collodion tinted with curcuma may be employed to give it a more yellowish tint. In the wet process a more yellow plate is required than in the dry. As regards the violet glass, it is preferred of a dark tint.

The printing of the three clichés with monochrome carbon tissue, of a red, yellow, and blue tint, is then proceeded with, or by any other mechanical process that is suitable, the impressions being secured, as recommended by M. Leon Vidal, upon translucent material; and the finished images are finally superposed, and should give a result possessing the same colours as the original object.

#### FAILURES IN CHEMICAL EFFECTS.

BY F. WALLER.\*

ONE of the most prolific causes of harsh negatives is a want of harmony between the bath and collodion. Where the sample of collodion is known to be good, and the productions are harsh and unsatisfactory, it will be generally found the bath has not been sufficiently iodized. In making a new bath, as it is a well known fact that a strong solution will dissolve more iodide of silver proportionately, it is a good plan to saturate your solution at a higher gravity than required for use, and then, weakening to the proper standard, the solution will be exactly iodized.

\* *The Photographer's Friend.*

Many will urge that the bath will then soon "kick up" and give pinholes, but careful addition of an uniodized solution at night, after work, will prevent that. And as most everyone has found the bath works finest immediately before giving pinholes, the nearer to complete saturation it can be safely worked the better.

Too much cannot be said against the use of strong developer, this being the most ordinary mistake; and the smallest quantity of acid sufficient to flow nicely is all that is necessary. The solution should not be dashed on, nor should the plate be rocked, except in cases where more density be required.

Every one has his pet formula for collodion, and one is as good as another, provided the proper relations are maintained between that and other solutions. Excessively iodized collodion I have not worked successfully with a weak bath, nor *vice versa*.

One cause of failure which has given trouble has been undue haste in the flowing of the plate. It should be held nearly horizontal, and kept so. There is no need of hurriedly tilting it back and forth: let it dry to a nicety, and immerse in the bath slowly, and allow it to remain at least a minute after being apparently coated. By this means the negative is of nearly equal density in all parts, and no streaks from imperfect coating can occur.

One word more as to the rectifying the bath. The iodine should be taken out very rarely, and injudiciously throwing down the iodine with water at each boiling is more apt to give trouble than prevent it. When the bath needs rectifying, the simplest plan is to neutralize carefully with ammonia; set in the sun until perfectly clear; boil down one-half; dilute to required standard with pure water; filter, and add nitric acid C. P.; if the bath is to be used at once, add considerable; but if it can be allowed to stand a short time, a small quantity will do. If upon trial it works harsh, but clean, flow the largest plate it will contain, and leave it in over night. Sometimes an acid bath will tog; if it should occur in regular streaks running across the plate in the same way the plate was dipped, the bath is not sufficiently iodized. Keep the bath well iodized, and it will need no tinkering; keep your collodion but a short time, and you will work quickly; keep your developer weak, and your negatives will be smooth and of a fine grain.

#### TURPENTINE IN NEGATIVE VARNISH.

BY JOSEPH UNGAR.\*

SPLITTING of the negative film is one of the chief banes of photography. It is true that means have been proposed to remedy the evil, the employment of an impalpable powder, such as soot and levigated graphite, aiding considerably when the defect is not too wide-spread; but the deposit of foreign matter in this manner has always an injurious influence upon the prints. Broad ruptures in the film cannot be remedied at all in this way, and the only means is to employ a pigment of some kind. But of the impressions taken from negatives doctored in this way the less said the better.

It would be a weighty problem to solve how many hundredweight of silver, either from inattention or lack of time and opportunity, find their way into the drains in the form of waste residues, and are lost for ever to the world. The amount would be something appreciable, but much greater and more important is the loss to photographers involved by the employment of bad varnishes. Every day, too, the loss is more severe, for the negatives of the present are often retouched at the cost of great labour and money. And yet the evil, notwithstanding its grave nature, is regarded with considerable indifference. Much has been spoken and written about the matter, and yet the plague exists, which destroys the collodion of our finest negatives. It may be asserted that

even the best studios suffer from this calamity. A German commission, which met two years ago to enquire circumstantially into the whole matter, did not arrive at any material solution of the difficulty. The multiplying process advocated by M. Obernetter, of Munich, is a most valuable method, no doubt, whose real value has not, perhaps, been fully recognized; but this cannot, unfortunately, be employed for all negatives that have been stored up for a considerable period. The great point is to pay particular attention to the nature of the varnish applied, and this is a subject which has never received the general consideration of photographers.

It is also to be regretted that the preparation of varnish is not in the hands of the photographer himself, and thus he has no control over its manufacture: its composition is kept a secret, and one must needs rely upon the good faith of the manufacturer. With other preparations one can judge pretty well what one is using, but with a varnish, the unsatisfactory results it may yield are not obvious until it is too late. We trust our most costly negatives to its influence, and when, after a shorter or longer interval, that arch fiend, daup, aiding the while, we find out our mistake, there is, unfortunately, no help for us.

The author has not essayed to combine any new recipes, but has set himself the task of watching for several years the behaviour of different varnishes in use, and with whose composition he was acquainted. As the result of his investigation he has found that those which, besides the lac, contained a good quantity of Venetian turpentine, have proved the most satisfactory.

In the first place may be mentioned the combination of two parts of yellow shellac and one part of turpentine, without addition of another resin, dissolved in weak alcohol. This is pointed out, not because it is absolutely the best, but because it is the one which by chance was first employed, and which has been tested for a longer period than any other, the negatives prepared with it being in perfect condition at the present moment. A number of clichés covered with this varnish have withstood the wear and tear of a voyage and six years. Against this varnish, however, may be adduced its brownish tint, which in places where it has been poured off the glass is rather thick, and causes longer printing, producing unequally printed impressions. Another objection is in its varying smooth surface, which renders retouching very difficult.

There are two other compounds, which differ from one another merely by reason of the amount of resin contained in them, gum sandarac being the principal constituent, the one containing one-third turpentine and one-fourth camphor, and the other turpentine to the extent of one-half and camphor to the amount of one-sixteenth. Both these are quite as excellent as the varnish first referred to, the latter of the two being especially to be recommended. Upon a film of varnish of this nature it is very easy to retouch, it being possible to work upon it with the hardest pencils of Siberian graphite without preliminary preparation of the surface. Plates of this kind may be allowed to remain for weeks in dilute nitric acid without the film being attacked in the slightest degree. To remove the film when the glass is required for use a second time, a warm alkali solution must be employed. In time the film becomes a little brittle, so that retouching after the lapse of years with a pencil may bring about a breaking up of the film. Splitting of the film, however, is only seen in those cases where great negligence has been present, and the plates have not been placed in paper envelopes and subjected to a moist or changeable temperature; but even then the defect is never seen to such a great extent as in the case of varnishes which are prepared without admixture of oil of turpentine.

The author has purchased a varnish which possessed the valuable property of not allowing the photographer to remain long in ignorance of his fate, and which produced splitting of the film within a quarter of an hour after its

\* *Photographische Correspondenz.*

application to the plate. This was rendered perfectly good by the addition of turpentine. Castor oil, which has also been suggested for a similar purpose, is, in my estimation, far behind turpentine as a preservative constituent of varnish. It seems not improbable that the turpentine adds much to the toughness of a varnish, counteracting the brittleness of the lac; and for this reason there can be no doubt of its desirability as a constituent of negative varnish.

At the same time this useful material may bring destruction with it. It is, however, in everybody's power to shield himself from injury, and we may here make clear a misconception in the matter. It has happened to many photographers that, on applying varnish to a warm plate, the film is dissolved away to such a degree that it is impossible to do anything with it in the printing frame, the effect being similar to that which would be produced if the unvarnished film was treated with ether or collodion. The cause of this is not unfrequently attributed to the bad composition of the pyroxiline in the image; but others attribute the fault to the alcohol in the varnish. If the first-named cause were really the true one, then all pictures prepared with the same collodion would be destroyed in the same manner when treated with varnish; but this we know does not happen. Generally speaking, a number of negatives are treated with good results, until, at last, the film of one of them, prepared in exactly the same manner as the others, suddenly gives way. No more can the alcohol be considered at fault, for in most cases a weak alcohol is employed for the purpose; and those even who, in order to accelerate the dissolution of the gum lac, employ absolute alcohol, are in the habit, subsequently, of adding water to bring down the strength of the liquid. But even if an alcohol of great strength were employed, this would not be capable of dissolving away the collodion film to the degree complained of. Destruction by means of alcohol is of quite another character. Poured upon a heated cliché, it causes that portion to become thinner, acting on the surface, indeed, like an etching fluid. On the other hand, if the varnish destroys the film, it does so by dissolving the same altogether, the silver precipitate flowing off in grey furrows.

It is clear, therefore, that some other agency must be at work, and this is, in truth, the case. Proof of this may be obtained very easily by the aid of a twenty-per cent. solution of Venetian turpentine in alcohol. If a well-warmed plate is poured over with this fluid, it is possible to produce a dissolving effect upon any collodion plate, no matter what the description of pyroxiline employed. The result is the more certain and rapid the more concentrated the turpentine solution happens to be. An increase in the temperature, and a stronger alcohol, favour the result in a great degree.

To ascertain how much turpentine may be safely added to varnish, we tried, for the purpose of experiment, a solution of equal parts of shellac and turpentine. The result showed that cold or slightly warmed films were not attacked by this fluid; the negatives might, indeed, be dried afterwards at the fire. If, however, the plates were heated, as is usual, prior to their being varnished, then the phenomenon of the film being dissolved was observed. This furnishes us with a reason why in a series of plates only now then an accident occurs; the plates must have been heated too much to withstand the amount of turpentine in the varnish.

According to this experiment about half, or little more, of turpentine than of lac, should be the maximum employed in varnish, and with this amount and a weak alcohol one may fearlessly operate, supposing the plates are not too highly warmed. This combination furnishes a very durable varnish. Our results are confined, it must be pointed out, to the combination of lac with and without admixture of turpentine.

We cannot, and do not, assert that there are not other

descriptions of varnish which possess higher qualities than the above, but only here note down, for the information of brother photographers, our experience in the matter, in the hope that they will reciprocate with information they themselves have gained; for I take it to be everyone's duty to contribute what he knows towards the longevity of our negatives.

In such an extensive field as ours, it is often the case that something escapes even the sharpest vision; while on the other hand another finds himself before the goal unawares, and has merely to stretch forth his hand to secure the prize. And so much has already been done in the cause of progress, by working together, that there is little doubt that if assistance is afforded on all sides, our arch enemy, that causes so much destruction among our negatives, will be at last successfully annihilated.

#### OUR PHOTOGRAPHIC PORTRAITS.

MR. BARNARD CRACROFT, one of the wittiest and most acute of modern British essayists, is the author of an article, originally contributed to the *Saturday Review*, on the "Art of Appearing Like a Fool with Propriety." It is full of the fruits of delicate observation of human nature, and of a most gentle and wise philosophy. We commend it to any of our readers who contemplate going, in cool blood, to have their photographic portraits taken. We know of no undertaking more trying to the average dignity and self-respect of, at least, the male portion of the human race, and no process more calculated to puzzle those who like to trace some connection between results and the means employed to produce them. Certainly, photographic portraits, as now taken by skilful operators, are a very pleasing thing, and not less surprising than pleasing. They are often attractive on account of the obvious delicacy and fidelity of the workmanship, and the evidences they afford of the manipulation of trained hands. But their attractiveness is by no means of this kind only. They are often very complete expressions of the character of the subject, which they present with simplicity and refinement. We have before us at this moment the portrait of an old gentleman, an artist, which is exquisitely true to a nature of the rarest purity and grace. The gentleness, the elevation of a mind wholly given over to the contemplation of the beautiful and the pursuit of a diligent and lofty art; the strength of an enthusiastic spirit; the animation flowing from a native shrewdness, keen sense of humour, a lively sympathy with human feeling, and a spice of vigorous but controlled combativeness—all these are in the picture, as well as the minute markings in the face of old age, the beauty of a snow-white beard, and the dignified carriage of a form broken with years and suffering, but sustained by a firm will. The gallery of the gentleman who produced this portrait is full of pictures of equal interest, and very varied in character. Actresses, singers, young girls, old women, fops, artists, politicians, students, roudés, clergymen, millionaires—the scores of people one meets on Broadway—are to be seen, many of them with faces marked by characteristic expressions or the equally characteristic want of it.

What inspires with wonder the observer who ascends from these to the operator's room, is how all this array of vivacious and expressive faces was turned out by the apparently barren and incongruous machinery of that illuminated den. The torn and rickety reflecting screens, the dingy velvet chairs, the rocks of wood and paper worn by the stream of human forms ("a continual dropping that weareth away a real stone"), the abominable racks and grips of iron—all these inspire one with a horrible sense of artificiality and arrangement entirely incompatic with freshness, or ease, or grace, or naturalness. This feeling is intensified when the observer is fairly "posed," his head twisted as it was never twisted before, unless by the photographer's merciless hands, and as it would never remain

were it not for the iron griffin that holds him in its unfeeling grasp, his eyes directed to a fixed point, and his whole system rebelling against the silent, rigid, despotic disposition of himself to which he has submitted. The skilful artist, with an occult purpose which one feels is doomed to disappointment, bids you to give your countenance a "little more animation." You grin in a ghastly way at the suggestion, when your sense of mortification at the figure you know you are making is broken in upon by your tormentor, who tells you with a comprehensive gesture—"That's it, precisely! Now let that dissipate into a genial smile, and I'll give you a good one." Mentally, you remark, that if he does give you "a good one," it will wear an expression of mingled idiocy and rage.

Yet the chances are nine in ten, if your photographer is among the best, that he will produce for you a portrait in which your friends will find a dozen different phases of your character. His experienced eye perceives the means of reaching the effect he is in pursuit of in arrangements that your uneasy consciousness condemns, and against which your pride rebels. Perhaps a rational man ought to be a little rebuked, a little touched with humiliation, at the reflection that he knows so very little about how he really looks. The conviction that one was really appearing with as much dignity and grace as were natural to him, when he felt that he was looking constrained and silly, suggests the awful possibility that when one appears to his inward eye all that he desires, he may be the very reverse to the impartial observer. There is a good deal of conceit in every kind of behaviour in the clutches of the photographer. The man, if not the woman, who can be unaffected and unconscious, who can feel that he don't look as if he cared for his appearance whether he does or not, to whom the photographer and his complex machinery for "posing" are only matters of study for a philosophic mind, is not a common phenomenon. Our old artist friend, whose bright and placid portrait we have praised above, may be one of them. But even the record of his consciousness might not sustain us in that bold assertion.—*New York Times.*

### APPLYING AND FIXING DRY COLOURS.

BY ROBERT FAULKNER.

THE following improvement received provisional protection only. It consists in mixing dry colours with dextrine or other suitable material, and applying it to paper, canvas, or other textile material, and subsequently moistening the back with water to fix the colour firmly in the texture. The specification is as follows:—

"My invention relates to a method of applying dry colouring matter, such as is employed for crayons, chalks, and the like, to porous surfaces, such as canvas or paper, and fixing the colour so applied. For this purpose I mix powdered dextrine with the powdered pigment, and I apply the mixture by rubbing in the manner usually employed for powdered pigments. I then moisten with water the back of the porous surface, and the water soaking through it dissolves the dextrine applied with the colour, and thereby fixes the colour. The water may be used warm or acidulated, so as the more readily to dissolve the fixing material.

"Instead of applying the pigment in the form of powder, it may be mixed with dextrine, and the mixture made up into crayons, which can be used for drawing on the surface. In this case the surface should be moistened before drawing thereon; when dry, the drawing will be fixed, or, if necessary, the back may be again moistened, so as to ensure the solution of the dextrine.

"I find it advantageous, especially for producing large backgrounds, such as are employed for photographic purposes or for wall decoration, and also when paper is the surface to be coloured, to serve it first with a weak solution of dextrine, and when it has dried to apply the pigments as above described.

"Instead of dextrine, starch, gum, or soluble gelatine may be employed in the manner described above; but I prefer dextrine, as being most readily acted on by the water.

"As the process above described essentially consists in applying along with the pigment a substance which is afterwards dissolved, and which, when dry, serves to fix the pigment, it may be readily understood that substances other than dextrine, gum, or gelatine might be used, suitable solvents being applied instead of water. Thus lac, resin, or other substances forming the ground of varnishes, might be applied with the pigments, and in such case the back of the coloured surface would be moistened with turpentine, benzole, or spirituous liquids capable of dissolving the matter so applied for fixing."

### COLOURED PHOTOGRAPHIC PORTRAITS.

BY J. E. PALMER.

THE following patent consists in a mode of colouring glass transparencies, or backing them with suitably coloured papers. The specification is as follows:—

"My said invention consists in certain improved methods of copying photographic pictures from negatives, and in colouring the copies so produced in oil or water colours, or shading the same in monochrome so as to possess great softness and artistic effect.

"In the first instance a transparent picture is obtained of the original size of the negative, or enlarged to any desired dimensions on glass or other suitable material, and the same is coated with a 'matt' varnish. The transparency is then placed against the light, with a sheet of tracing-paper covering the same, and the outlines of the picture traced on the said paper with a lead pencil. The tracing-paper is then placed with the pencil marks against the glass, and the pencil marks retraced with the lead pencil on the other side of the paper; grey crayon is then rubbed on the outlines on the side first traced, and the whole placed on drawing paper of the desired grain, slight pressure being used by a pencil or other instrument over the outlines until the whole of the outlines are marked on the paper. The shading and colouring are then commenced; crayons, oil or water colours, powder colours, prepared chalk, or other suitable materials being employed on the said paper as a packing, and placed against the photographic transparency, thus forming by its combination a fine artistic effect; nicety of touch in applying the aforesaid materials is not necessary, as the matt varnish acts as the softener.

"If clear varnish should be preferred to the matt varnish, Reigate silver sand, or Calais sand, or some similar substance, or substances is or are used to assist in the distribution of the crayon or powder colours, but should not be pressed so hard as to abrade the surface of the paper, as a grain of a very artistic quality is produced by that of the drawing paper alone.

"For the further carrying out of my invention, I use photographs for the backings of the said transparencies, my mode of proceeding being to make designs in artistic shaded effects in oil, water colour, pencil, steel, or zinc engraving, or stone in stipple, etching, fine grain, landscapes, interiors, and other suitable designs on canvas, paper, or other material, making photographic copies of the same on albumenized or plain paper, or other suitable material, leaving a white centre suitable to receive the photographic transparency, and softening and blebbing the photographic design into the edges of the said transparency by means of the aforesaid crayons, powder colour, oil or water colours, giving an effect similar to that produced in the ordinary way by double photographic printing. In the case of albumenized paper being used, I float the same with the matt varnish, making thereby an easy surface to receive the colours, and on the photographic designs on plain paper, if to be in oil colour, I prepare the paper to receive the same with size in the usual way.

"Having thus declared and ascertained the nature of my said invention, and in what manner the same is to be performed, I would observe, in conclusion, that what I consider novel and original, and therefore claim as constituting the invention secured to me by the said hereinbefore in part recited letters patent are:—

"1st. The combination of a photographic transparency with or without matt varnish, with a backing on paper or other material, with effects produced on the said backing, substantially as hereinbefore described and set forth.

"And secondly. The combination and backing up of photographic transparencies with photographic designs, and blebbing the same to produce a perfect appearance to the eye, substantially, as hereinbefore described and set forth."

## AMERICAN PHOTOGRAPHS.

FROM the earliest days of photography the devotees of the art in the United States have taken the lead in technical and manipulative excellence; but it is only of late years that they have asserted an equal supremacy in art culture—or, if not supremacy, at least equality. If they do not lead in art photography (at least so far as it is applied to portraiture), they do not follow. From time to time we meet with examples from all parts of the Union which are equal, in every quality of excellence, to the best work of the best men in the Old World. We have recently had a pleasant opportunity of examining a series of portraits rarely equalled, either in interest or excellence, the special circumstances giving the examination a peculiar zest. An American lady, spending some months in this country, attended a course of class lectures by Professor Huxley, who declined to accept a fee from the fair student. The lady conceived the happy idea of acknowledging the courteous liberality of the Professor by presenting him with an album containing the portraits of distinguished men and women in America, and commissioned Mr. C. D. Mosher, of Chicago, to prepare an album with such a selection of portraits. We are indebted to the lady's courtesy for a sight of this album, and also for acting as intermediary in transmitting some very beautiful examples of Mr. Mosher's photographic and literary work.\* A very handsome album, filled with very perfect cabinet photographs of heads, all in greater or less degree distinguished, and distinguished looking, full of character, force, and intelligence, constitutes a gift which cannot fail to gratify the Professor more than the fees of many students, probably initiating a host of shadowy friendships one day to be consummated by personal intimacy.

Our special object here is to note some important points in which much of the American portraiture which we have seen of late excels the average of English work of a presumably similar class. We have been struck, on comparing recent English portraiture by high-class artists with the portraiture under notice, to notice the cold, hard, flat effect which the former presented. Let us be understood: they were not cold, hard, or flat absolutely in themselves; they would, in fact, be regarded, both by photographers and the public, as fine pictures. The negatives had been carefully retouched, and the heads had fair modelling and texture; but it was the modelling of stone, the texture of marble, not of flesh; whilst the American pictures to which we refer have the texture and modelling of living flesh, which

would present a warm touch, and yield with a soft elasticity if the finger were pressed against it. There are English artists who recognize the necessity of preserving the suggestion of the natural texture and quality of objects; but, unfortunately, a great many fail to do so, in greater or less degree, especially in ordinary commercial work. In the last photographic exhibition we had examples of both kinds of work. In the pictorial work of Mr. Rejlander and Messrs. Robinson and Cherrill, in the portraiture of Mr. Blanchard, in the enamels of Mr. Mayland, and in some other admirable contributions, the quality to which we refer was present. It is not necessary to refer to special examples of its absence. We refer to the unsatisfactory fact in general terms simply to suggest to all portraitists a more careful consideration of the subject. At one time there was a demand on the part of the public for flat, white faces, and photographers met that demand the more readily because the hard lighting, full exposure, and much intensifying, removed many blemishes which would otherwise have been offensively prominent. Many of those who undertake the retouching of negatives seem to aim at a similar standard. They produce a smooth, white face, with little of texture, shadow, or modelling. One of the really valuable elements of the practice of retouching is found in the fact that it permits soft lighting and the use of thin negatives, giving full texture and modelling, the pencil of the retoucher removing those defects which the thin negative would otherwise render too apparent.

Another advantage of the soft lighting and thin negatives to which we are referring is the beauty with which it permits the rendering of light draperies, white hair, &c. In some of the noble heads before us by Mr. Mosher we have admirable illustrations of these points. Silky grey hair, in which every single hair is defined, without interfering in the slightest degree with the massing of the waving locks. Shirt collars and fronts, too often a chalky patch, distracting the attention from the face, are here low in tone, with every curve, fold, and wrinkle duly rendered, reminding us of Ruskin's dictum, to the effect that not even the space of a pin's head in any natural object will be found without some degree of gradation. The light draperies of ladies—whether of silk, muslin, tulle, lace, or other fabric—receive the same justice. Whilst we are indebted to Mr. Mosher for a series of admirable photographs of noble and attractive heads, we shall be glad if some of our readers gain hints and suggestions, not because their work is necessarily bad to begin with, but because there is better work to be done than some of them at this moment are producing.

Some recent examples of the work of Kirtz, Sarony, Notman, Inglis, and others, all point to the same conclusion—admirable lighting with plenty of shadow: thin negatives, and a large, judicious style of retouching, which preserves the luscious soft texture of living flesh, instead of the minute, over-elaborated texture of marble, are present in all. Cabinets appear to be the prevailing size, and large heads the prevailing style. They are for the most part printed in oval medallion, with a tinted margin to the medallion. In some the margin, instead of having a plain tint, have a diaper design, and in some a fine delicate veining similar to white marble, and this, by its suggestion of hardness and polish, gives additional value to the quality of the flesh texture. In almost every instance they appear to have been finished by the aid of Weston's burnisher, the enamel-like surface it communicates materially aiding the effect of detail on the pictures.

## THE COLLODIO-CHLORIDE OF SILVER PROCESS.

THE recent interesting papers by Mr. Bruce and Mr. Hooper on the collodio-chloride process, and the very beautiful examples of results exhibited as produced by its aid, have brought us many communications on the

\* A capital little work by Mr. Mosher is entitled "Half-an-hour's Chat with My Friends." We shall have something to say about it shortly.

subject, asking if no English manufacturer will undertake a similar branch of trade to that pursued by Obernetter and others with advantage on the Continent. It will be obvious to correspondents that the discussion of commercial enterprise in such matters is beyond our province. That ready facilities for purchasing the collodio-chloride paper ready for use would be a boon in many instances there cannot be a doubt. The beauty of the pictures cannot be questioned, nor have we ever heard of a case in which their superiority in permanency has been denied by any one who has worked the process, or even tested it, the allegations as to lack of permanency having been chiefly based upon anonymous gossip or untrustworthy hearsay. As to the absolute permanency of the results of the process, a period of longer than ten years will be necessary to determine; and in fact, it is doubtful whether absolute permanency can ever be predicated with certainty of any image produced by the salts of silver, nor indeed of the results of any process imperfectly or carelessly worked. But we have collodio-chloride prints in our possession, both on paper and glass, which we produced, before the process was known to anyone but ourselves, in 1864, which are now quite unchanged.

The chief difficulty in the commercial application of the process is the trouble entailed by preparing the paper. If ready prepared paper of good quality were easily accessible, there is little doubt that it would be much more extensively used. We have been favoured by Mr. Inglis, of Montreal, with some exceedingly charming examples of his portraiture printed on collodio-chloride paper prepared by himself. He remarks that the "soft richness of collodio-chloride prints" is, in his opinion, "very far superior to anything obtainable upon albumenized paper." His difficulty is in carrying out the process on a large scale with all the paper to prepare in his own establishment. He says:—"Where two or three hundred cards per day only are required, the process can be managed well; but where from a thousand to fifteen hundred prints a day have to be got through, it is difficult to do the work and prepare the paper." Nothing can exceed the neatness and delicacy of the examples we have received from Mr. Inglis, and we can well understand his regrets that better facilities do not exist for introducing the thing easily on a commercial scale.

Mr. Faulkner writes in a similar strain. After some compliments, which we shall not quote, on the boon which he thinks we "so generously conferred on the photographic world," he proceeds to details. He says:—"Should you require at any time illustrations of the superior permanency of collodio-chloride pictures over ordinary silver prints, I shall be happy to supply some. In a frame consisting of upwards of forty pictures, which I exhibited at Conduit Street four years ago, in the centre is a collodio-chloride, printed nine years ago. All the ordinary silver prints were printed carefully, and toned to the collodio-chloride print as a standard. All the ordinary prints have faded more or less, but the collodio-chloride print retains even the fine bloom which it, in common with silver prints, possessed at first." Other communications have a similar tendency.

We have been favoured with a note from Mr. J. W. Swan, on the subject of the addition of citric acid to the collodio-chloride as an aid to additional vigour in the image, the first use of which we recently accredited to Mr. Bovey. Mr. Swan, who has, from the time of our publication of the process, given it considerable attention, and has, we believe, continued since then to manufacture the emulsion, reminds us of his early use of citric acid, and his communication to us upon the subject. Without the slightest desire to deprive Mr. Bovey of the credit, he asks us if any record of the use of this acid in connection with the emulsion exists anterior to his (Mr. Swan's) intimation to us. At this distance of time, upwards of nine years, we feel it difficult to say absolutely which commu-

nication reached us first. In our early experiments increase of vigour chiefly depended on the use of excess of nitrate of silver in the emulsion, which when used on opal glass involved some inconveniences, which we described. So far as our memory serves us, both Mr. Swan and Mr. Bovey suggested the use of citric acid independently, but which was first we cannot, without minute reference, determine. We may add, that Mr. Swan certainly first tried the result of developing a slightly exposed collodio-chloride print, and, we believe, first used the emulsion for reproducing negatives.

To the amusement, rather than the surprise, of his readers, our British contemporary indulges in his hysterical protest as to the origin of the process, and with hysterical energy denies our claims to its discovery, which he, as usual, attributes to M. Gaudin. Of course, we have no intention of entering into any discussion on the subject, M. Gaudin having himself disclaimed the matter, and assured us that after he had suggested it, amongst other emulsion processes, he was unable to succeed in putting it into practice. As a correspondent points out on another page, no one has yet undertaken to say that he had either seen or heard of a collodio-chloride print until we published our process. Our contemporary states that he has before denied our claims: it is but justice to him to say that he has done so, and it is a little hard upon him that as he has done so, often and energetically, no one believes him, and no single photographer of reputation or position has ever been found to endorse his assertions. His form of assertion reminds us of that of Dogberry—"Masters, it is proved already, . . . and it will go near to be thought so, shortly."

#### SIMPLE METHOD OF PRECIPITATING SILVER.

AMONGST the various methods of precipitating silver from waste solutions, none is more simple, and, for some purposes, none more efficient, than the plan of placing strips of copper or zinc in the solution, which gradually precipitates the whole of the silver in solution as a black metallic powder, ready for conversion, by means of dilute nitric acid, into nitrate of silver. For transforming old and contaminated nitrate baths into pure nitrate, and so securing a new, pure bath, nothing can be simpler, easier, or better; and in many cases such a course is, doubtless, better than prolonged attempts to restore working qualities by means of doctoring. One probable reason why many photographers do not attempt methods of precipitating of this kind is the fact that they have not the facilities in the shape of strips of pure zinc or copper at hand. Our American friends, ever ready in ingenious methods of supplying wants, and so creating trade, have already devised means to meet this desideratum, and we find an article in an American contemporary describing the "metallic precipitating bars," which have just been introduced into commerce there. A demonstration by the "inventor" is described. "A portion of a disordered bath was furnished, and into it was put one of his metal bars. In a very few minutes the silver was all precipitated in metallic form; a small quantity of hydrochloric acid was then added to dissolve any small pieces of zinc which might have become detached. The precipitated silver was then worked in a few changes of water, and immediately dissolved with nitric acid. The result was a solution of perfectly pure silver. This mode of treating disordered baths has been adopted by some of our most experienced photographers: all who have tried it have been highly gratified with the result. To still further simplify the process, we have had manufactured a quantity of these metallic bars, bent in the form of a U, of half an inch in thickness. This will obviate the necessity of adding any acid after the silver is precipitated to dissolve any metal which might have become detached, as was frequently the case when thin sheet zinc was used. All that is necessary with one of these bars to purify your

bath, is to place the bath in a suitable vessel, put the bar into it, with a string attached for convenience of removing it. In twenty or thirty minutes the silver will be all precipitated; not one grain need be lost. Two or three washings, and dissolving with nitric acid, reducing to the strength you require with distilled water."

Probably many photographers will not find it difficult to provide themselves with convenient bars by means of application to any worker in zinc; and probably some of our dealers may find it worth while to keep a stock of such things for supply to their customers. Suitable bars of a U shape will, doubtless, materially facilitate the operation of precipitating silver in this way. The dark metallic powder should always be washed in one or two changes of dilute sulphuric acid, to remove all traces of zinc, and afterwards in two or three changes of clean water, one of which may be warm, to remove the sulphate of zinc, before dissolving the precipitate in nitric acid to obtain the pure salt for a new bath.

The same method is applicable to the reduction of chloride of silver and old hyposulphite solutions; but in such case the precipitation is slower, and may be materially aided by connecting the bars with a galvanic battery. For such mode of reduction Mr. F. Hart's apparatus is admirably adapted.

#### ELIMINATING HYPOSULPHITE BY MEANS OF ACETATE OF LEAD.

THE use of acetate of lead for eliminating hyposulphite from washed prints has been again under discussion at a recent meeting of the Photographic Section of the American Institute. Mr. H. J. Newton, who was in the chair, protested against the report recently published as that of a committee of the German Photographic Association of New York. The report, which we published some weeks ago, stated that prints treated with the acetate of lead had, after twelve months' keeping, faded and turned yellow; whilst other simply washed prints, produced at the same time, had retained their pristine brilliancy. Mr. Newton is not satisfied that the prints upon which this report is based were really those experimented upon by the committee, and, as the subject is of considerable interest and importance, we give the same publicity to his protest as we did to the report. He says:—

"It does not appear from this report that these were the same prints that were cleaned by the committee. The secretary did something afterwards, and exhibits those as faded prints. I had used this process for several years before I published the article, so as to be perfectly sure that I should not lead any one into trouble. I make nothing out of photography—what I give to the photographic fraternity is perfectly gratuitous—and I was desirous that others should test it at that time, and made a pretty emphatic request in that paper that they should report, so that we all might have the benefit of their experience. Eight or nine months after that, there were some pictures sent to Mr. H. T. Anthony by a photographer in Massachusetts, who, as soon as the article was published, prepared some prints in both ways, put them in a show-case, where they would be subjected to the direct sunlight for a large part of the time, and those were sent to me, through Mr. Anthony, after they had been so exposed for seven or eight months to the light of the sun and the action of the weather; and the one cleaned with the lead never changed one particle, and has not to this day, although it has been in my possession for two years; while the one that was fixed and washed in the ordinary way turned yellow. That is a case that runs exactly counter to the report of this secretary—for it is not the report of a committee, but the report of the secretary of a society, who was chairman of the committee at the time."

Mr. Newton gave the successful experience of others who have used the lead salt, and showed various prints

which, having been treated with it three years ago, were free from any signs of change. We have often pointed out that however perfect the washing may be, it will not prevent the fading of prints in which the elements of change have been planted by imperfect or careless fixation; and Mr. Newton echoes this opinion. He observes:—"A print may be perfectly cleaned from hyposulphite, and yet fade. Fix a print in hyposulphite used four or five times, and, I don't care how much you wash it and clean it, it will fade."

Mr. Chisholm and others gave testimony in favour of the lead treatment, thus confirming the evidence of various correspondents in our own pages.

#### COLOURING PHOTOGRAPHS.

A CORRESPONDENT of the *English Mechanic* gives some hints on colouring photographs; but commences by a protest against the practice of colouring photographs at all, and especially without the skill of a practised painter. For those who are anxious to make the attempt, he gives the following hints.

"Nearly, if not quite all the various colours used in painting may be made from the five colours, black, white, blue, red, and yellow. In the majority of cases, the following will be found sufficient, viz., carmine, Prussian blue, white, chrome yellow, gamboge for drapery; yellow ochre for the face, or all three; light red, indigo, burnt sienna, bistre or burnt umber. If in a colouring any part of a lady's or gentleman's apparel, it is found necessary to produce other tints and shades, the following combinations may be used—Orange; mix yellow with red, making it darker or lighter by using more or less red. Purple: this is made with Prussian blue, or indigo and red. Carmine and Prussian blue make the richest colour, which may be deepened in the shadows by a slight addition of indigo or brown-green. Prussian blue and gamboge make a fine green, which may be varied to suit the taste by larger portions of either, or by adding white, burnt sienna, indigo, and red, as the case may require. Brown may be made of different shades of umber, carmine, and lamp-black. Neutral tint is composed of indigo and lamp-black. Crimson: mix carmine and white, deepening in the shaded parts of the picture with more carmine. Flesh-colour: the most like is light red, brightened in the more glowing parts with carmine, softened off in the lighter portions with white, and shaded with purple and burnt sienna. Lead colour: mix indigo and white to suit. Scarlet: carmine and light red. For jewellery, cups of gold and silver preparations may be procured.

"In colouring pictures the principal shades of the head are to be made with bistre mixed with burnt sienna, touching some places with a mixture of carmine and indigo. The flesh tints are produced by the use of light red, deepened towards the shaded parts with yellow ochre, blue, and carmine mixed with indigo, while the warmer or more highly coloured parts have a slight excess of carmine or lake. Colour the shades about the mouth and neck with yellow ochre, blue, and a very little carmine, brightening the colour of the lips with carmine and light red, letting the light red predominate on the upper, and the carmine on the lower lip; the shades in the corner of the mouth being touched slightly with burnt sienna mixed with carmine. In colouring the eyes be guided by nature, observing a very delicate touch in laying on the colours, so as to preserve as much transparency as possible. A slight touch of blue—ultramarine would be best—in the whites of the eyes near the iris will produce a good effect. In colouring the hands of men it will be necessary to use the darker tints with more freedom according to the complexion of the sitter. For women the warmer tints should predominate, and in order to give that transparency so universal with the softer sex, and which gives so much loveliness and beauty to the face, a little white may be intermingled with

he red tints about the lighter portions of the face. The roots of the hair at the forehead should also be touched with blue, and the eyebrows near the temples made of a pinkish tint. The chin of a woman is nearly of the same colour as the cheeks in the more glowing parts. In men it is stronger and of a bluish tint, in order to produce the effect given by the beard. In portraits of women the middle tints on the side of the light, which are perceived on the bosom and arms, are made of a slight mixture of ochre, blue and lake (or carmine), to which add, on the shaded sides, ochre, bistre, and purple; the latter in the darker parts. The tints of the hands should be made the same as the other parts of the flesh, the ends of the fingers being a little pinkish, and the nails of a violet hue. If any portion of the fleshy parts is shaded by portions of the dress, or by the position of the hand, this shade should be coloured with umber mixed with purple. To colour the drapery—Violet velvet: use the purple made of Prussian blue and carmine, touching up the shaded parts with indigo blue. Green velvet: mix Prussian blue and red orpiment, shade with purple, and touch up the lights with a little white. Red velvet: mix a little brown with carmine, shading with purple, marking the light in the strongest parts with pure carmine, and touch the most brilliant slightly with white. White feathers may be improved by delicately touching the shaded parts with a little blue mixed with white. White muslin, linen, lace, satin, silk, &c., may also be coloured in the same way, being careful not to lay on the colour too heavily. In selecting brushes, choose those susceptible of a fine point, which may be ascertained by wetting them between the lips, or in a glass of water."

#### ON THE STABILITY OF COLLODION FILMS.

BY DR. H. VOGEL.

I HAVE made a series of trials on the influence of quality and quantity of cotton, of development, fixing solutions, varnishes, preliminary coatings of plates, &c., on the stability of films, in the interest of the forthcoming observations of the transit of Venus, and I give here a short account of my results, which may be, perhaps, of some benefit to the observers. The details of my experiments may follow in the next.

The contraction of films depends very much on the quality of cotton. The cotton which delivers a thick collodion and tenacious film generally contracts much. I have tried different cottons, and found that the contraction was the least in the "celloidin" cotton of Schering, Berlin. This is the best for astronomical purposes. The contraction depends upon the quantity of cotton in the collodion. The contraction is diminished in a remarkable degree by dilution with alcohol and ether. The collodion of Maun, St. Petersburg, with two per cent. of cotton, gives a contraction of  $\frac{1}{30000}$ ; diluted with half its volume of alcohol and ether, it shows no further remarkable contraction.

3. The adhesion of the film on the glass is of great influence. If on any part the film loosen the glass during washing or the film is injured a little, there is a tendency to contraction or variation of the preliminary dimensions. Therefore it is necessary to work on plates with a preliminary coating of albumen or india-rubber. On such coating the film does not loose the surface, and even a little damage is without influence. Only albumen dry processes do not want any preliminary coating, because the films with the albumen preservative are very stable.

4. All preparations which induce the film to loose the surface (as gums) are of bad influence.

5. Acid pyro development induces strong contraction of the film if it lays on plain glass; but not on albumen plates or plates coated with india-rubber, if sufficiently exposed. Under-exposed plates, very long developed, change in a remarkable manner.

6. Alkaline development gives no tendency to contraction.

7. Dry plates are more stable than wet plates. The

best results I got with albumen plates (Fothergill) and with morphine plates on preliminary coating with india-rubber.

8. Some varnishes change the dimensions of films: mastic varnishes the least. The experiments in this direction are still continued. One sample of varnish (Beseler varnish, made in Berlin) gives no change at all.

9. Fixing is of no influence on the dimension of films if there are not bodies like gums, which induce blisters.

For coating plates with india-rubber I dissolved one grain rubber in one hundred grains chloroform, separated the clear portion of the whole after three days, diluted with ten volumes pure volatile benzole, and filtered. The plates are washed, dried, brushed, and coated with the rubber solution in the ordinary manner.

#### RECOVERING SILVER FROM WASTES.

BY JEN. BARDWELL.\*

IN 1855 and 56, I was engaged in working the dry plate process—and you recollect, in those days, we made very intense negatives with perfectly opaque skies—using the honey, gelatine, and other processes, and the manner in which we worked wasted an awful quantity of silver solution in the developments. I used to develop my plates of an evening, and used a large tray to catch the waste and slop; and in the morning, after having developed several whole plates, would find quite a quantity of silver precipitated, which, after pouring off the spent developing solution, would remain on the bottom of the tray. This, of course, set me thinking, and I commenced from that time to save my waste washing, &c., using my developing solutions for that purpose, pyrogallie and gallic acid, iron and the sulphides, until about the year 1859 and 60, when I found a much more satisfactory way of doing it, so much to my satisfaction that I have had the method in constant use ever since. It is easy of application, cheap, has no bad odour, and requires very little attention, and is, in fact, the ne plus ultra of silver saving apparatus. I might have had it patented, perhaps could now, and, in fact, I am sure I could if the same rule would hold good in my case as in others.

However, to the description. The first thing required is a keg holding (say) fifteen to twenty gallons for small galleries, and larger, or, perhaps, better, two or three of them, and in very large establishments, barrels should be used. These kegs should have faucets set in about one-third the distance from the bottom, and a large hole cut in the head for pouring into it the washing waters, &c. These kegs are then to be filled with scrap zinc (which can be got of any tinman cheap). The zinc should be cut in the strips and slightly bent or twisted, to prevent the pieces from laying too close together, and the kegs should be filled to the top with these pieces, and are then ready for use. We will say, for instance, there are two of these kegs. After printing the prints are washed; this washing water is poured into the keg, also the hypo, after having fixed the prints, and, in fact, any solution containing silver may be poured in, in the same manner, until the keg is full; then commence with the second. Three kegs will not be required unless you fill one a day, and when it is full, empty the first by the faucet (provided it has stood at least two days) into a vessel, so that the precipitate that will fall from the zinc in drawing off the liquid may be saved. The precipitate will be saved in any manner most convenient. This is all that is required, but observe not to pour any acid mixture on the zinc (this does not apply to the washing waters containing acetic acid).

The zinc will last a long time, but when it does waste and settle, keep it filled up with fresh strips. In my practice, after collecting the precipitate, it should be well washed, to free it as far as possible from hypo, salt, or any soluble matter that may be retained by it, and then dried.

\* *Anthony's Photographic Bulletin.*

I now take a large iron ladle and put into it some of the dried precipitate, and roast it to a red heat, which will drive off and consume considerable sulphur and zinc, and make the reduction more easy. When at a red heat you will notice at times coloured flames arising from it; continue the heat so long as they make their appearance, then empty the ladle and continue until you have it all roasted, then pulverise the roasted precipitate, and when cold mix with two parts of powdered saltpetre (pure), and proceed to reduce to a metallic state by the Hadow method. This, in connection with the method of reducing, may seem complicated in print, but in practice is of very little trouble, and will save many a dollar to him who works it.

### A WORD FOR OUR PROFESSION.

BY W. HEIGHWAY.\*

THAT it is a branch of the fine arts, is the honourable boast of those of our number who have a love for their work, and ambition above the sordid consideration of dollars and cents; but there are by far too many who have no just conception of or care for the higher claims of art, and tinkering along a daily routine of careless, botchy work, merely regarding it as a trade by which they can subsist with less labour than by following heavier trades, for which they might be better adapted. No wonder, then, with so many of these evidences of perverted skill (?) constantly before them, that the public misjudge the merits of our beautiful art, and degrade it to the level claimed by this miserable mediocrity.

It may be urged by some that this objection is a very fanciful one—that it matters little what is thought of us by the public, so long as they come to us as sitters, and pay their money. Individuals advancing such an opinion take to themselves credit for a great deal of philosophy, that they are able to take such a high and independent ground. But, in reality, is it not rather grovelling than noble, and is it not our duty to strive to gain the good opinion of the world in an honest and manly way?

We should treat all our visitors in an uniformly courteous manner, not toadying to the rich and influential, and snubbing the poorer of our customers; adopting politeness and uniform attention to all, not as a policy that pays, but as a duty to ourselves as gentlemen. That you will reap a benefit from it, there is no doubt, and, in addition to this pecuniary advantage, you raise the tone of your business, and tend to an advancement of the profession.

Not one of the less active of the causes of the low estimate the public take of photography as a profession, is to be found in the constant parading of vulgar jealousies; that public washing of dirty linen, alas! too common amongst us. Let us never fail to speak with the greatest possible respect of our competitors and their work. Instead of petty sneers and insinuations of ugly things, which are mean and contemptible, let us speak of our rivals as we would they should speak of us. Our listeners can discriminate between the utterances of jealousy and the expression of fair and honest criticism; and the eulmiator, believe me, does not benefit himself, but only brings discredit on the profession. A little more politeness and charity, and a little less jealousy, would tend greatly to our advancement in the respect of the public.

The time has come when our profession depends on the highest order of culture, thought, and art knowledge, for our customers are becoming more and more enlightened in art matters every day, and bring fine discriminating powers to bear in judgment of our work. It is necessary for us to be ahead of them, or we shall find ourselves deserted of all our friends; while we shall see Mr. Jones, across the way, who does keep up with the times, who does think and act on his artistic knowledge, and is of gentlemanly deportment, has his gallery filled with satisfied patrons.

\* Philadelphia Photographer.

Read the journals devoted to photography. You may not be able to see how much you gain by it; you may even doubt if you have gained a single "wrinkle;" and perhaps you may believe you know more than the editor and all his staff put together. But even in this unpleasant state of mind, read. Read all this "trash and nonsense;" it tends to elevate the mind, and in that way, if in no other, it does you good.

### Correspondence.

#### THE GELATINO PELLICLE.

DEAR SIR,—Dr. Nicol has expressed his surprise, in a contemporary journal, that so little has been heard of late respecting the new pellicle; and Mr. Kennett has again invited those who have tried his preparation to give the result of their experience, whether successful or otherwise. As nearly three hundred photographers have been supplied with the preparation, I suppose each one is waiting for his neighbour to begin. Having assisted at the birth of young pellicle, and even been assured by his anxious parent that I stood in the position of godfather to the promising youth, I naturally feel interested in his advancement, and hasten to relate what I know about him.

My first experiments were by no means successful. Knowing the extreme sensitiveness of the preparation, I drew the curtain in front of my dark room window; and lighting a mere spark of gas, shaded by an orange-coloured glass globe, I proceeded to coat the plates. When I had got through this, and laid them carefully on a flat table, I left the room for a few minutes for some purpose—only to find upon my return that my assistant had turned up the gas; as he observed, he wanted to see—that was all. Unfortunately, it was not quite all, as the plates had seen the light also: in fact, the whole batch was spoiled. The first three or four we tried we could get no image at all; and after that, the rest were faint or fogged.

One of my early mistakes was in pouring the emulsion on the plates without warming them, causing the film to dry unevenly; the next was over-exposure. Following the formula for dry work, I gave about half as long again as for the ordinary collodion process (for the inventor had no idea at this time of the great rapidity of his plates). The exposure was really about ten times as long as it should have been. In both these cases I was misled: in one, by the directions; in the other, by the want of them. As Mr. Kennett is to read a paper on the subject at the next meeting of the London Photographic Society, I hope he will favour the photographic community with the most minute particulars; starting with the idea that the larger portion of his audience know absolutely nothing of the gelatine process, which differs in many respects from the ordinary collodion work—and where, from the extreme sensitiveness of the material, the least error may be fatal to the work. A new set of directions is wanted. By perseverance I succeeded in overcoming the principal difficulties.

All who have seen the specimens exhibited must have admired the fineness of the film and clearness of the image—"Chiare, fresche, e dolci," as Petrarch expresses it. The extreme rapidity also must be manifest to those who have persevered so far as to obtain a perfect image. In the fraction of a second required to flash a light upon the negative and prepared plate, I have obtained by contact printing a perfectly exposed transparency; even by gaslight I found three or four seconds sufficient. With regard to the exposure for negatives out of doors, this extreme rapidity is manifest enough.

I must here state that my experience in working other dry plates is very small indeed, and that of the most recent date. "Comparisons," as the learned Dogberry assures us, "are odorous;" and it may appear invidious to compare the pellicle plates with those of another sort; however, it is only by doing so that we are enabled to judge of their different qualities and degrees of excellence. The only other dry plates that I have seen in use were some half-dozen of Colonel Wortley's 10 by 8 size, prepared by the Colonel himself, and exposed by Mr. Crawshaw and Mr. H. P. Robinson, when upon a recent occasion I partook, in company with yourself, the generous hospitality of Cyfarthfa Castle. The plates were exposed in the fresh mountain air of Talybont—time from thirty-five to fifty-five seconds. Upon being developed next day, they were found to be slightly under-exposed; those that had the longest time being the best. Of course, with my limited experience, I do not give this as the average of a Wortley plate: I merely speak of what I saw. The weather, too, as you will

probably remember, was heavy, and the clouds charged with rain, of which we had soaking proofs before we reached home. I believe, however, that with the pellicle plates used under the same conditions an exposure of four or five seconds would have sufficed.

I will not further take up your valuable space. Those who have succeeded will require no encouragement to perseverance: to those who have not succeeded, I would quote the little song, familiar to most of us in our juvenile days, and if they "find the task is hard," I certainly advise them to "try, try again." They will have some difficulties to encounter, especially in keeping light from the plates; but I believe, in the end, they will be rewarded by the results. Fortunately, they can do this at a very small cost. Mr. Kennett has been advised by his friends (myself included) to raise the price of his preparation to something like a level with that of his predecessors; but, although out of pocket by his invention, he has not done so. I hope, therefore, the qualities of young pellicle will be amply tested during the short interval of fine weather which we in England have agreed to call summer.—Yours truly,  
R. W. ALDRIDGE.

221, Cornwall Road, Notting Hill, W.

#### MAGIC LANTERN IMPEDIMENTA.

DEAR SIR,—It seems that Mr. Nicol has taken the Scottish motto, "Nemo me impune lacessit," as his maxim, and, under the pretence of a fatherly solicitude for the pockets of your readers, attempted to requite me for upsetting his hobby. But he has laid about him in so random a manner, that his blows have all fallen upon his friend Mr. A. He places himself in a false position when he judges and condemns that with the first principles of which he does not appear to be acquainted. He has misquoted the passage in my article of April 17th, concerning the blue glass, which was intended to be quite supplementary, and only to be used when required; nature offering green as the colour most suitable to afford repose to the weakened sight of the invalid or over-tasked worker. The trial papers I sent you show that light green glass permits more light to pass through it than orange.

Taking the ounce as the unit of weight and measure, the quantity of water I stated in reply to "Oxygen" will be found correct, whether it is subdivided by the standard pint of sixteen ounces, or the imperial of twenty ounces. I find that this duality of measures gives an opening to a practice of which it may benefit your readers to be made aware. Retailers make a practice of buying by the latter and selling by the former; and I find that the gallon jar is not made of any greater capacity than it used to be.

I freely accept Mr. Nicol's proffered hand, and he must please to consider himself hobbled-nobbed with spirit whiskey or a cnp o' barley brew in right old Gaelic (or, should he be a brother of the craft, in true Masonic) style; and I hope to see his name in the PHOTOGRAPHIC NEWS coupled with some subject worthy of his talents and position, and that there will be no need to caution your correspondents, in the words of Burns—

' If there's a hole in a' your coats,  
I rede ye tent it;  
A chiel's amang you takin' notes,  
An' faith he'll prent it.'

A little brush, as Mr. Nicol terms it, is only robust exercise to an athlete; but mere wrangling is out of place in an educational work like the present. The fear of being involved in a wordy warfare, or incurring the risk of unmerited castigation, too frequently prevents a timid mind from offering ideas which might prove highly beneficial to the public.

It does not appear that any progress has been made towards the accomplishment of the object desired: the ingenious duplex automatic gasometer of Leo would, I expect, prove too bulky to be portable, and to maintain pressure, water would, I suppose, have to be poured occasionally into the upper compartment. To those of your readers unaccustomed to the use of gas, the following hints may prove useful. Safety in a great measure depends upon a sufficient and continuous pressure being maintained upon the gasometer or bag during the consumption of the gas, and it must be perfectly under the control of the exhibitor. No increase in size of the bore of the jet will supply the want of this, but rather increase danger. Beyond a certain degree, pressure should not be exceeded, as this would only cause a useless waste of gas. When making gas, reject a close stove, and use a common open fire grate in preference.—Yours truly,  
JAMES MARTIN.

5, Clarence Place, Ilfracombe, June 2nd.

#### THE COLLODIO-CHLORIDE PROCESS.

SIR,—A recent letter in the Liverpool journal, signed "A. L. Henderson," laments that Mr. Hooper did not think it worth while to make himself acquainted with the history of the collodio-chloride process before reading a paper on the subject. Those who live in glass houses should not throw stones. Mr. Henderson's name is notorious amongst photographers for two or three things, none of which qualify him for throwing stones with advantage. Whenever anything new or beautiful has been introduced to photographers, he has been among the first to detract the claims of the process or its inventor. He has himself claimed a process of enamelling, the suspicious originality of which has prevented him from securing it by patent, but the secret of which he has preserved carefully, after in vain trying to sell it for a thousand pounds. He has claimed, as a novelty, adding nitrate of baryta to the silver bath, a thing which had been proposed publicly many years prior, and the efficacy and results of which, as claimed by him, have been denied and disproved by men like Mr. Tunny and Dr. Nicol. Other points on record in his public career need not be mentioned now. Mr. Hooper is doubtless able to answer for himself; but being the most energetic of the opponents of the defeated requitists, of whom Mr. Henderson was one, he would probably have enough to do if he noticed every petty attack upon him. At any rate, he is manifestly better acquainted with the history of the collodio-chloride process than Mr. Henderson, who attributes it to two gentlemen who neither discovered it nor claimed it. The actual history of the process is too well known for discussion, and not one of the barking detractors of the discoverer has ventured to affirm that he ever either saw or heard of a collodio-chloride of silver picture until it was announced in your pages in 1864.—Yours truly,

FAIR PLAY.

#### ON BURNISHING PHOTOGRAPHS.

SIR,—If you refer to the PHOTOGRAPHIC NEWS of August 29th, 1862, you will find in Answers to Correspondents that I sent you specimens of photographs wherein you state the finish is very excellent.

The said photographs were burnished by means of an iron roller drawing the photo. over a hardened steel plate, and the pressure regulated as desired. At that time I finished all my photographs by these means, but had to be careful to keep the photograph free from grit, or else it was marked, and required extra labour to produce the desired result. I merely write this so that you may see the new invention you commented on last week is very near related to an old one of  
J. LOSH.

[In "Weston's Burnisher" the photograph is drawn over a rounded burnishing edge, which increases the effect, whilst it enormously decreases the risk of abrasion. But there doubtless appear some points of analogy in the initial idea of the two presses.—ED.]

#### Proceedings of Societies.

##### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of this association was held on Tuesday evening, the 26th ult., at No. 15, Oldhall Street, the Rev. H. J. PALMER in the chair.

The minutes of the previous meeting were read and passed.

In reference to the spoiling by the spirit varnish of some negatives taken by Mr. Bolton's process,

Mr. W. KEITH said that a second negative need never be lost from that cause, as, whenever it was found that the varnish attacked the film, or the plate happened to be dirty, it was only necessary to give the negative a coating of thin gum solution.

Mr. ATKINS said that he had used gum, and also albumen, with good effect.

Mr. KEITH then minutely described the capabilities and construction of Ross's new symmetrical lenses, and Mr. ATKINS handed round a pair of No. 3 for inspection. The lightness and portability of the lenses, and the fact that one flange (of about an inch and a half aperture) was sufficient for the whole series, was considered to be great inducements to their adoption by all field photographers, especially as, by merely changing the stop, different angles of view could be obtained.

Votes of thanks were passed to Mr. Keith, for his interesting information, and to Mr. W. Atkins, for his kindness in providing a room to hold the meeting, the usual meeting room at the Free Library being closed for cleaning.

## The Photographic News, June 12, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

INTERNATIONAL SCIENTIFIC LIBRARY—RECREATIVE SCIENCE—LIMOGES ENAMELS—NEW MODELS FOR THE PHOTOGRAPHER.

*International Scientific Library.*—A scheme has recently been started by a number of scientific men in this country, as also in France and Germany, to bring out a series of scientific works which shall appear simultaneously in the English, French, and German languages. Whenever an author of note in any of these countries contemplates publishing a work on a subject which may be deemed of sufficient importance, an endeavour will be made by the promoters of this plan to induce the writer to allow them to prepare translations of the book, so that it may be printed at the same time in London, Paris, and Berlin. The idea is certainly a good one, and, if only the subjects are well chosen, there cannot be a doubt of the success of the enterprise. Four volumes have already appeared, by Tyndal, Schmidt, Bain, and Bagehot, and we hear that one of the next works is to be from the pen of Dr. Vogel, on the subject of photography.

*Recreative Science.*—One may laugh as much as one likes, but it is a singular fact that the popular mind, as represented at fairs, races, and other gatherings of the sort, always takes kindly to science whenever presented in a tangible form. The capacity of your lungs, your lifting power, your weight, and the amount of electrical strain your nerves can undergo, are matters which the public are always anxious to learn about, if we may judge from the large patronage bestowed upon the investigators of these subjects. In like manner the travelling photographer has come to be regarded as quite a component part of all popular gatherings, and the smart outfit and brilliant apparatus used by some of the more well-to-do operators often secure for them unlimited custom. A shilling for a small glass positive, or half-a-crown for a group in a carriage at the races, leaves plenty of margin for profit, doing the work conscientiously. Indeed, there is quite a respectable class of peripatetic photographers now springing up, so well does this kind of enterprise pay. Lately, we came across a still further advance of science out of doors, in the shape of a green baize stand, upon which stood a valuable binocular microscope of handsome proportions, its bright brass work and shining lenses glittering in the sun. Twopence was the price charged for a peep through this wonderful instrument, and, doubtless, the amount of curiosity and love of the unknown, possessed by many to so marked a degree, would bring the learned microscopist costs of customers.

*Limoges Enamels.*—We have heard nothing lately of the revival of the enamel art at Limoges. As our readers are aware, Limoges enamels attained at one time a very great name, and collections of them at the present day are very valuable, by reason of their extreme beauty, as also from the fact that the art of making them has been entirely forgotten. Some time since, it may be remembered, the professor of chemistry at the Limoges College hit upon the happy idea of reviving the art again in conjunction with photography, and set about investigating the subject with the idea of blending the old with the new, and thus bringing back to Limoges the beautiful art for which it was once so famous. Although, however, a couple of years have now elapsed, no further steps appear to have been taken in the matter, and we fear that the difficulties to be overcome have proved too much for the good people of Limoges.

*New Models for the Photographer.*—There is a rare feat awaiting performance by some clever photographer who has pluck enough to attempt it. It is no less than to secure a picture in the camera of the great sturgeon which

now lies almost motionless in one of the tanks of the Brighton aquarium. Mr. Henry Lee, the well-known naturalist of that institution, assures us that the royal fish remains for hours in a state of perfect repose without moving a hair—or we should say, rather, turning a scale—the whole time. The tanks, being lighted from above, are most favourably illuminated for photographic purposes, and as, moreover, there is no visible current of water, there is really nothing to mar a long exposure. A gigantic pike inhabits a neighbouring tank, which might also serve as a photographer's model, we feel sure, for at times it affords a wonderful example of "still life." Submarine photography is no novelty, we are aware, for some time back an apparatus was devised for illuminating and photographing the bottom of the sea, although we never heard of the same being much used. At any rate, no monsters of the deep have yet been photographed alive, to our knowledge, and here, therefore, is an opportunity which should not be lost. It is a pity an instantaneous picture cannot be taken in the same way as Dr. Gayer photographs live animalculæ, placing a strong light behind the tiny creatures as they swim about, which actually shines through their transparent little bodies.

### RAIN WATER.

BY WILLIAM H. WATSON.

PURE water—oxide of hydrogen—is prepared from natural water by distillation. Water, however, as it exists in nature, is a much more complex substance, and as it has somewhat important relations to photographic art, some of your numerous readers may be interested by the conclusions arrived at from several of my analyses of rain collected under different circumstances. It will be seen that the quantity of solid matter contained in rain water is according to the purity of the atmosphere through which it has fallen: it being contaminated, near the sea, with sea salts, carried by the wind as spray; or in towns contaminated with sulphates, carbonic acid, ammonia, &c. With this view, it will be remembered, Dr. Angus Smith, some little time ago, proposed to form a climatology, and suggested a process for the examination of atmospheric air.

The purity of water is a matter which must not be overlooked in photography, especially in its application to the dry processes. In consideration of this subject we should look at the preservative, which may be done under two different lights:—

1. That in which it is desired to increase the sensitiveness of the film, from which all the nitrate of silver has previously been washed, as in the tobacco process, which I suggested to you a few weeks ago.

2. That in which it tends to act as a restrainer in a process where a considerable quantity of silver salts remain in the film.

Taking view No. 1, the first thing to be done is to wash the plate with water immediately it is removed from the bath, and afterwards to allow it to remain in the water for some time. If we use for this purpose water containing a considerable amount of solid matter, constituted to a great extent of chlorides, we have at once a chemical combination with the silver and the chlorine, forming chloride of silver, the chlorine having a greater chemical affinity for the silver than for the sodium or magnesium bases with which it was combined in the water. Or suppose the solid matter to contain much organic matter, the result is an organic salt of silver, which, being insoluble, will penetrate the film, there, very probably, to form a complex compound with the iodide, and afterwards to perform its injurious effect on the plate.

I will now refer to my note-book for the examination of the samples of rain.

*Sample No. 1.*—Rain fallen about a mile from the sea, in the country:—

Total solids ... ..	4.57	per 100,000 parts
Containing chlorides ...	1.47	
Sulphates ... ..	0.96	
Organic matter ... ..	0.21	

Sample 2.—Rain fallen about fifty yards from the sea, and about one hundred and twenty yards above sea level:—

Total solids ... ..	17.10	per 100,000 parts
Containing chlorides ...	15.60	
Sulphates ... ..	1.23	
Organic matter (say) ...	0.26	

Between samples 1 and 2 we note a difference of 12.53 solids and 14.13 chlorides.

Sample 3.—Rain fallen at Bolton-le-Moors:—

Solid matter ... ..	6.30	per 100,000 parts
Containing chlorides ...	2.00	
Sulphates ... ..	1.83	
Organic matter ... ..	0.70	

It is a prevalent idea, I believe, suggested by Faraday, that snow is much more free from impurities than rain; and this may be easily understood if we consider that a flake of snow does not, as a drop of rain, come into contact with the atmosphere—only the outer portion. I append my analysis of a sample of snow fallen about a mile from the sea:—

Total solids ... ..	1.94	per 100,000 parts
Containing chlorides ...	0.96	
Sulphates ... ..	0.40	
Organic matter... ..	0.10	

#### MONTHLY SPIRIT OF THE JOURNALS.

BY W. H. DAVIES.\*

WHEN I undertook to bring together as an experiment, and at the request of the committee, a monthly spirit of the journals, I little thought of the trouble this would involve, and I can only hope that the next volunteer who takes it up may be able to give you at once a more practical and a more useful digest than I have done. I have necessarily left undone many of the things which ought to have been noticed; and in condensing these extracts I have been unable (through want of time mainly) to connect them as I would have liked; so you must take the will for the deed.

Aniline colours have been again recommended for the purpose of tinting photographs and photographic paper. I do not seriously object to their use, but remind those who wish to try that, when used as pigments on silver prints, they are the most unstable of all colours, as the folios of many a dealer in coloured photographs could show.

Mr. Carey Lea wishes to know what will remove the stains of alkaline pyrogallic acid development from the fingers. I think if he tries he will find that with warm water, tartaric acid freely applied with a brush will overcome his difficulty, followed by sand soap, or, still better, pumice and rubber sponge.

The melancholy position into which the London Photographic Society has drifted, and the quantity of leading articles and correspondence on the subject, induce me to suggest that if the parent society would adopt the rule that exists in ours, of one-third of the council retiring annually, and those being incapable of re-election for a year, their greatest difficulty would be overcome. A good addition to this might be a reduction of the number of their vice-presidents, and their removal by seniority in the same way. Whether a limitation of time should be applied to the holder of the president's chair is a more delicate question; but our rule of annual election, with the liberty of re-election, is a sound and a healthy one, and one that would obviate every difficulty. Of course, in a national society, proxies must be allowed, even although they are often made a wrong use of.

Mr. Gordon Ramsay suggests the use of three small

rubber umbrella rings on the corners of the triangle, to save scratching the bottom of the camera. I would like to ask him to fit these to the more usual circular tripod head, and he would find it difficult. These loose rings he would also find a nuisance if he lost or forgot one of them. Let him try my plan as shown to this society three or four years ago, of getting a groove cut in the solid iron or brass on the top, and therein inserting a strip of vulcanised rubber projecting all round slightly; he will then find that not only will he have secured his darling camera from scratching, but he will also find that the adhesiveness of the rubber has made his camera a great deal firmer and more rigid.

At the meeting of the Photographic Society of France, April 10th, M. Ferrand, member of the French Aeronautic Society, begged the P. S. of France to photograph a bird in the act of flight. The chairman said the thing was impossible; nothing but a blur could be got, which would teach nothing; but still the society could try the experiment, and he himself meant to try. Do so, Mr. Ferrier, and if you are as successful as our townsman, Mr. John Lennie, has been, you will have nothing to regret. His stereograph of the sea-shore with a flying gull was simply perfect; it was taken at least ten years ago.

A claim has been made by that careful experimentalist, Mr. Carey Lea, for an improvement in collodio-bromide plates, by the omission and the introduction of albumen into the preservative, and so forming an albumenate of silver in the film. Apart from chemical reasons, which have been dealt with by the Editors of the *British*, there are other good reasons why washing may be dispensed with, and albumenates of silver formed in the film. Assume an accurately balanced bromide emulsion without excess of nitrate, and all that is wanted to make the preservative flow easily is one of two things: either such a partial evaporation of the solvents of the collodion before dipping into the preservative bath as would allow easy covering and penetration by it of the film without decomposition, which, I think, may be easily managed; or, by adding, as I have done repeatedly, spirit of wine to the preservative (beer and albumen), or to any other containing albumen sufficient to allow the collodion and preservative to attach themselves to each other, and the thing is done; all that is wanted is to give time between coating the plate and applying the preservative. With such a preservative, which is of the nature of a varnish, it is well to use a little alcohol in the developer, to allow of more perfect penetration by the developing agents. On these and other grounds, I see every reason to hold that Mr. Lea is right as to dispensing with washing collodio-bromide films, and I only wait, not for more, but really for a little leisure to test and verify what I consider a great advance in dry plate work.

What has been said as to the throwing down of the albumen, &c., seems to me of little force, since I know by long past experiments that it is possible to combine albumen directly with collodion to the great advantage of the negative, the only requirement being the exposure of a large surface of albumen to an aqueous sample of collodion, combined with agitation and gentle heat; and with collodion so treated, no preservative whatever was required, the washing of the plate being sufficient to produce an admirable dry plate. Many other reasons, of course, might be adduced; I mention these only because they have not yet been noticed. The question of the formation of an albumenate of silver in the film seems to me to be an extremely easy one to solve, and one which has often been solved in the albuminous dry process.

The introduction of Ross's new symmetrical lenses calls for a word of notice. Has any one seen or got one of these lenses? From their description, they are made after the Steinheil fashion, but corrected for colour. One can't be always buying new lenses, some of which, after all, sometimes turn out no better than the old. My impression of these, from a

\* Read before the Edinburgh Photographic Society.

cursory examination of one of them, is, that the principle upon which they are constructed is good, and that they ought to supply a felt want. If, as stated, they give finer definition than the doublets introduced in 1864 by Mr. Ross, they will be fine indeed, for one of my best lenses is of that make, and I have not met its match, in any lens whatever, for that particular quality.

Weston's rotary burnisher has been mentioned, and I bring you a few prints to show the action of the instrument. I may mention that I think it frightfully dear. The burnisher itself seems to be made from chill-cast iron. It is said to be an alloy, not steel, and it looks more like chilled cast iron than anything else I know. The prints must be finished in the touching before being burnished, otherwise the touching shows very badly. The slightest speck of dust, also, is fatal to the effect.

Have any of our ardent experimentalists tried the dusting on blacklead process so fully described this last month? If so, we should like to see or hear of the results; but the same want of time I have referred to has prevented me trying it.

Matzner's developing process for albumenized prints was read before the Vienna Society. This, shortly stated, consists of silvering the paper by immersion in a silver bath which has been acidified with citric acid ten per cent., printing till the print is visible, then developed face down, by saturating it with distilled water—adding a lot of glacial acetic acid, and when quite wet, add saturated gallic acid, and, if necessary, a few drops of silver. Surely this is not such a discovery as to need the reward *the inventor* (save the mark!) wished the society to present to him for publishing it.

The agreeable French Correspondent of the NEWS, in speaking of the coagulation of dried albumen on paper, and of M. Thierré fils, of Bresles, having succeeded in accomplishing it by the addition of alcohol to the bath (no new addition), should know that this is a perfectly easy thing to do, and that to a certain extent it is done commercially. I brought before this society, a number of years ago, the method invented by Mr. Wood, of this city—viz., acting on the paper with steam in a closed chamber, varying times being used according as the albumen is wished to be more or less completely coagulated. I have made the albumenized surface so hard by this process, that the paper became quite waterproof, and have found it impossible to get the silver to adhere to or penetrate the surface. Some mechanical uses might be found for such paper, say for waterproofing the inside of dishes, &c. Photographic use it has none; but where the coagulation is less complete the surface is improved, the bath does not discolour, and the paper is in every way improved; but it is rather slow to tone. The ordinary double albumenized paper of commerce is prepared in this way for the first coating, the second being done in the ordinary way, by flotation, or in some cases by brushing very carefully to avoid bubbles; and in this way a very brilliant surface is produced.

Such are a few of the points I have thought worth noticing for discussion this evening, or for calling attention to in order that they may be tried, and, if found right, added to our stock of knowledge; and if found wanting, sent to the limbo of forgetfulness.

#### GERMAN CORRESPONDENCE.

THE TRANSIT OF VENUS—OBSERVATIONS ON THE CONTRACTION OF THE COLLODION FILM—COATING PLATES WITH INDIA-RUBBER—THE MORPHIA PROCESS—NEW ALBUMEN PAPER COMPANY.

BY DR. VOGEL.

The summer advances, and the nearer the term approaches for the great astronomical event of this year, the more zealous are the preparations carried on in all the civilized countries of the world for the proper observation of the same. Here

also trials for photographing the sun are in progress, and many a photographer who hears of it puts to himself the question, why are so many experiments necessary?—photographing the sun is an easy matter. This is very true; nothing is easier than taking a picture of the sun; but the matter assumes an entirely different aspect when a picture is to be made which admits of very exact measurement, for in this case the pictures themselves have to be mathematically correct, and most photographs are in this respect deficient. They cannot be mathematically correct, because (1) most lenses distort a little; (2) because the collodion film, by the developing, intensifying, drying, and varnishing processes, becomes somewhat changed, and the original picture is altered in its proportions. This change in the collodion film makes all measurement illusory, no matter how small it may be, for the question is to measure fractions of the seconds of an arc. If, for instance, we take the size of the whole sun, equal to 1800 seconds, and we take a picture of four inches diameter, then one second is equal to  $\frac{1}{1800}$  inch, but the intention is to measure  $\frac{1}{10}$  of a second =  $\frac{1}{18000}$  inch. How is this possible if collodion contract  $\frac{1}{10}$ , as Pashen has demonstrated, or, in other words, seven times as much as the size which is to be measured?

It is a question of the utmost importance to find a film which does not contract. Rutherford, the celebrated astronomer and photographer, has published also his observations on the contraction of the collodion film. According to him the matter is not as bad as represented; it amounted to only  $\frac{1}{10000}$ . This surprising discrepancy in the statements of Pashen and Rutherford induced me recently to investigate this subject myself, and I found that the contraction varies considerably with different samples of cotton. There are samples of cotton which contract very much, while others possess this quality in a lesser degree. I found that thick collodion contracts the most, while the limpid ones much less. Of all the kinds which I have tried, Schering's collodin-collodion contracted the least. The contraction varied also with one and the same sample, according to its concentration. The same collodion which, with two per cent. of pyroxyline, showed a contraction, did not show any with one and a-half per cent. If no collodion is to be had, it will be necessary to employ a diluted collodion.

Fothergill's dry-plate process has been proposed for taking the pictures of the transit of Venus; it is said to furnish very stable films. The stability, however, is not due to the process, but is owing to the small amount of cotton present in the collodion; for the collodion which is employed in this process contains but 0.9 per cent. of pyroxyline.

Still another point exercises an influence—i. e., the addition of the film to the glass. When the film is very firm, the adhesion is slight; and when the adhesion is slight, there is danger of displacement. When, for instance, the film becomes detached from the corners of the glass during the washing, and water gets between the film and the glass, the former will become changed in shape. The same result follows when the film becomes in any part of it broken or perforated. Every means which increases the adhesion of the film to the glass lessens, also, the distortion, and *vice versa*. Hence, albumenizing the plates before collodionizing is beneficial, as well as coating with caoutchouc; while, on the other hand, gum substances, when placed upon the film, become detrimental, for these cause a raising of the film during development, and hence distortion; and it follows that all the dry-plate processes in which gum is used as a preservative are not suited for work of this kind. Those who desire to employ a dry-plate process should select one in which the preservative, after having been poured on, is washed off again—as, for instance, with albumen—or where the preservative is so much diluted that it cannot exert an injurious influence. Very suitable for this purpose is pure morphia (not acetate of morphia). One gramme of morphia, when boiled with

seventeen hundred and fifty grammes of water, yields a preservative which makes a washed iodide of silver plate very sensitive, without exercising any injurious influence on the stability. I have tried, further, to find out what influence an alkaline developer exercises on the film. It has often been stated that an alkaline developer loosens the film and causes contraction. This, however, takes place only when a gum is on the film; otherwise, the alkaline developer does not affect the film, and is even, in some respects, preferable to the acid developer; for when the collodion film is treated for a long time with pyrogallic acid, it will always contract, as is readily seen when we intensify with pyrogallic and silver solution. The alkaline developer is, of course, only suitable for certain plates (chloro-bromine process). The preparation of the plate is not a success in everybody's hands.

I hope that the hints which I have given in the above lines will not be too late for the Venns expedition. Perhaps they are important, also, for the preparation of all plates where exact measurements are necessary—as, for instance, the reproduction of cartoons, &c., &c.

I have spoken above of caoutchouc solution for coating plates, and will mention now how the solution is best prepared. One part of finely-cut india-rubber is dissolved in one hundred parts of chloroform. It takes two or three days until the solution is completed; one part remains undissolved, and floats on the top; the clear solution is drawn off with a glass tube, and is diluted with ten times its volume of pure and very volatile benzine. The solution is placed on the cleaned, dried, and dusted plate before coating the same with collodion. The plates may be kept for a month, in a place free from dust.

The morphia plates which I have mentioned above deserve particular attention on account of their sensitiveness. It is not at all difficult to make morphia plates which are nearly half as sensitive as wet plates, but the most curious part is its sensitiveness for colour. While ordinary bromo-iodide collodion plates are sensitive only as far as green (beginning from the violet of the spectrum), morphia plates show a sensitiveness which extends as far as the red and into it. This circumstance is of great importance for photographing the sun, for the edge of the sun emits relatively more reddish yellow and green rays than the centre, and with ordinary collodion the edge appears often under-exposed. Morphia plates, however, do not keep long; even after four days the sensitiveness begins to diminish. This has, of course, nothing to do with photographing the transit of Venus, as the day when it occurs is well known. The morphia process which I now practise is as follows:—

(a.) *Collodion.*

Bromide of cadmium ... ..	1 gramme
Iodide of cadmium ... ..	1 "
Alcohol ... ..	25 grammes

Filter, and dilute with three times the volume of plain collodion containing two per cent. of cotton.

(b.) *Nitrate Bath.*

Nitrate of silver... ..	100 parts
Water ... ..	1000 "
Iodide of potassium ... ..	$\frac{1}{4}$ part

(c.) *Morphia Solution.*

One gramme morphia boiled with 1750 cubic centimetres of water for one hour.

(d.) *Pyrogallic Solution.*

Pyrogallic ... ..	1 gramme
Alcohol ... ..	10 grammes

(e.) *Citrate of Silver Solution.*

Citric acid ... ..	1 part
Nitrate of silver... ..	1 "
Water ... ..	50 parts

(f.) *Fixing Solution* as usual.

The plate is collodionized and placed for at least three minutes into the silver bath; it is afterwards dipped in distilled water and well washed. It is next placed for three minutes into the morphia solution and dried.

For the purpose of development, the plate is placed into diluted pyrogallic solution.

Pyrogallic solution ... ..	1 part
Water ... ..	20 parts

The picture appears feebly; the plate is taken out and developed with pyrogallic, to which *very little* silver solution (c.) has been added. If the plate has been over-exposed it is advisable to take more silver solution. The development progresses very slowly; only, after all the details have appeared, more silver solution should be added to the intensifier.

In conclusion, I have to communicate to you some important news. The eight or ten different establishments of Dresden for the production of albumen paper have been consolidated, and form now one single albumen manufactory. The enterprise is a stock concern. We will in the future only have one source in Dresden from which we can obtain albumen paper, and the factory has only one competitor in Germany, namely, Trapp and Munch, in Friedberg (Hasse). It is said that the principal party which supplies plain paper (Blanchet freres in Rives) is interested in the undertaking. This event may become of great importance for photography. If a factory which furnishes such an important article as albumen paper has no competitor it will be able to dictate terms. There are, of course, other establishments outside of Germany which manufacture albumen paper, but none of them are so extensive as those of Dresden. Of the fifteen hundred reams of paper manufactured weekly by Blanchet freres in Rives, one thousand went to Dresden for the purpose of being albumenized; the balance was distributed through the other states. At present we have, besides Blanchet, only one factory where plain paper is made, namely, the one of Steinbaeh in Malmedy, where the Saxe paper is made. So far this paper has been considered inferior to the Rives paper; perhaps the new arrangement will give an impulse to his establishment, for I should feel very sorry if we were dependent on one establishment for the supply of plain paper.—*Philadelphia Photographer*

ON AN IMPROVED DRY PROCESS.

BY M. CAREY LEA.\*

THE dry processes known up to the present time divide themselves naturally into two very distinct classes: those, like the Taupenot, Fothergill, English, and other processes, in which the chief constituent of the preservative is albumen; and, on the other hand, those, like the gum-gallic, the tea, pyrogallic acid, tannin, and other processes, in which no albumen is used. The albumen processes have certain well-marked and excellent characteristics, but they are all slow, and require long exposures. Nevertheless, it has been found for some years past, in England, where dry plate work is very popular, that a large proportion of the best prints exhibited were made from negatives belonging to the class of albumen preservatives.

On my return to America last summer, I commenced a series of experiments to ascertain whether the advantages of these two different systems could not be combined, and whether a satisfactory rapidity could not be imparted to albumen plates, whilst preserving their delicacy and fine modulation. In this attempt I have recently succeeded, even beyond my hopes, and have obtained a process differing in all its essential features from any now in use. It is a collodio-albumen dry process, and yet as rapid as the wet. At the same time, in simplicity and

\* *Philadelphia Photographer.*

quickness of manipulation, I believe I may say it exceeds all other dry processes.

Before proceeding to the details, I may be permitted a few words of explanatory preface.

When, in the year 1866, I first took up the study of the emulsion process, several formulæ had been published, and some of these called for the presence of silver nitrate in excess of what is needed to decompose the soluble bromides in the collodion. But at that time the silver nitrate was always added in powder, and much of it did not pass into solution. There was a tendency for the grains of nitrate, instead of dissolving, to become coated with silver bromide, and then to resist the weak solvent power of the collodion. I introduced the system of dissolving the silver nitrate by heat in a portion of alcohol, and adding this to the bromized collodion, and at once agitating violently. In this way all of the silver salt was got into solution, and then I found that whenever the silver nitrate was present in excess the plates invariably fogged. After a continued research, I found that this could be obviated in two ways: either by the introduction of a chloride into the bromide collodion, or by the addition of aqua regia. The latter I gave the preference to, and the general experience of photographers during the years that have elapsed since then has confirmed that opinion. Sometimes, indeed, an advantage is gained by combining both methods.

The behaviour of the emulsion made with silver nitrate in solution proved absolutely that up to that time no plate had ever been made with silver nitrate in excess. The excess had lain at the bottom in powder, and inert. Its doing so was all that saved the plates. Had it dissolved, they would have fogged. The addition of a chloride, or of aqua regia, first rendered it possible to use silver nitrate in excess, and the gain in sensitiveness was immense. At first the extent of the advantage was hardly recognized, but latterly it has been thoroughly appreciated. In describing the action of aqua regia, I stated that any amount of excess of silver nitrate might be employed, but that I found the best results came with a small excess. I regret to say that shortly after a most unexampled attempt was made to appropriate my process on the strength of simply varying the proportion of silver nitrate. By some this variation was held to be an improvement, whilst other photographers found that they succeeded best with my formulæ. Whilst these discordant results in no wise justified the attempted appropriation, the fact nevertheless remained unexplained, why such different conclusions should have been come to by different experimenters.

It was not until some time after that I succeeded in solving this enigma. I found that different preservatives required very different proportions of silver nitrate. Up to that time it had been customary to recommend one and the same proportion of silver, no matter what preservative was to follow. This system was essentially wrong, for each different preservative has its definite proportion of silver salts with which it gives its best results. The less sensitive the preservative, the larger the quantity of silver nitrate which it requires.

For a long time I had worked with the cochineal preservative which I had proposed. This is the most sensitive of all preservatives known up to this time; it therefore requires to be worked with a very moderate excess of silver nitrate; if more be used, the plates are found to solarize easily, and if at all over-exposed, are found to intensify with great difficulty.

Subsequently I tried pyrogallie acid, and got very excellent results. This substance proved to be less sensitive than cochineal, but I found that this inferior sensitiveness could be compensated for by increasing the nitrate, which increase was borne in this case, though it would not have been in the case of the cochineal. By further experiments

I succeeded in establishing the general law that I have stated above, viz., that the less sensitive the preservative, the larger the proportion of silver needed for it. So that we have a regular series, cochineal, pyrogallie acid, gallie acid, and tannin, diminishing in sensitiveness from the first to the last, and each member requiring considerably more silver than the next member before it.

As albumen is a preservative considerably less sensitive than any of the four just mentioned—less sensitive, even, than tannin—it is clear that if it be used in the preservative bath the dose of silver must be very large, in order that we may obtain a high degree of sensitiveness; and it also follows that this large dose will be borne without those inconveniences that accompany its use with the more sensitive preservatives. This is to be expected, even if the albumen be mixed with more sensitive preservative agents; for, as I have already shown elsewhere, when two preservative agents of different degrees of sensitiveness are mixed, the result will be a degree of sensitiveness conferred intermediate between the two, but rather inclining to be less sensitive.

Applying this principle, I succeeded at once in obtaining very sensitive albumen plates—indeed, far more sensitive than any one would have believed that albumen plates could be. It is needless here to give the formula, since it has been superseded by a further improvement which I have just made, and shall now describe, and which is a complete departure from all existing methods, both in principle and in practice.

The albumen plates which I first made were prepared in the method usual with emulsion plates. The glasses were edged, and then coated with emulsion, plunged into water, and washed till the greasy lines disappeared, then passed into the albumen preservative, and dried.

(To be continued.)

THE USE OF PHOTOGRAPHY IN SURGICAL AND MEDICAL SCIENCE.—A medical correspondent of the *English Mechanic* writes to suggest the use of photography in medical science. He is probably not aware that the subject has been more than once brought under discussion. Some years ago the late Dr. H. G. Wright called attention in our pages to the subject, appealing to photographers to aid in forming a public medical library by sending all examples of photographs of anatomical and physiological studies, especially abnormal cases. The correspondent of our contemporary in question says:—"A use of the wondrous photographic art has occurred to me as likely to be of great value in medical and chirological science. Perhaps it has occurred to others also; but a humble practitioner in a remote western hamlet has but little intelligence of what passes in the great world. More than once, in a rather long practice, I have met with examples of abnormal structure so instructive, that I have been fain to have recourse to a professional miniature painter to represent them. Yet so extreme was the need of accuracy, so foreign were the subjects to the experience of the artist, and so repulsive were the conditions under which they were set before him, that several guineas was the lowest *honorarium* demanded on each occasion. Now a photographer would reproduce the case in a few minutes, and that with an accuracy absolutely perfect; while, if he took a stereoscopic picture, the presentation would have an aspect of reality incomparably beyond any production of the painter. This, then, would be of great value. But I was further led on to consider the application of photography, and particularly of stereography, to the illustration of normal anatomy; to the representation of the muscles, the vessels, the nerves, the viscera; of the organs of sense, *in situ* and dissected-out; of tissues, sane and morbid; and this, whether in natural dimensions or magnified. Thus would the physician or surgeon be ever accumulating, at small cost, absolutely perfect illustrations of those demonstrations which years ago charmed and taught him in the dissecting theatre. Precious as is his costly Quain, or Swan, or Haller, these stereoscopic pictures would be vastly superior, because infallibly trustworthy, and the student could select such as bore on his special practice."

## THE LONDON PHOTOGRAPHIC SOCIETY.

THE final meeting of the present session of the Photographic Society of London was held on the evening of Tuesday last, and the plethora of matter of interest, and the full attendance on a warm June evening, gave full evidence that the *raison d'être* of the society continues in full force, and that if any decadence arise, it is not to lack of interesting subjects, or lack of interested members, it can be attributed. A stormy, and in some respects worse than wasted, session comes to a close with little effected, beyond the restoration of the bulk of the old officers who had felt compelled to resign, and new blood in similar proportion to that which, had been elected at each annual meeting for many years back. These officers have considerable work before them during the recess, on the satisfactory completion of which, some hope may be entertained that a new session may open in the autumn, to be devoted to the legitimate business of the society, with the jarring antagonisms of the past few mouths put aside for ever.

No announcement regarding an exhibition has been made to the members, for the simple reason, we believe, that no decision has yet been come to in regard to it, the newly elected council having had neither time nor opportunity either to discuss or arrange the matter, although it has not escaped their attention. A strong feeling, we know, exists on the part of many members of the council on the importance of a specific effort to secure an exhibition in which no falling off shall be manifested. The maintenance of its annual exhibition is doubtless one of the most important and valuable of the society's works. The misfortune is, that when time and energy are frittered away in wretched squabbles, legitimate work inevitably suffers. In many cases, too, the confidence of members is shaken, doubts arise as to whether an exhibition will be held, preparations for contributions are delayed, so that serious risk exists of the possibility of securing a successful exhibition. It is to be hoped, however, if the council see the possibility of holding an exhibition, due effort will be made by contributors to prevent it falling below the high standard of displays of the last few years. We presume that some early intimation as to the determination will reach all concerned.

The revision of the laws, as Mr. Spiller announced on Tuesday evening, is another important subject which is occupying the attention of the council, and a revised draft will doubtless be shortly in the hands of every member. A special meeting must, of course, be held soon afterwards, for the purpose of considering and passing the laws in their new form, the final decision of any moot points being doubtless left to the vote of the members at large. After the adjournment of the meeting on Tuesday evening an attempt was

made to open a discussion on this subject, Mr. Hughes asking by what right the council attempted to prepare any revised draft of laws, a committee having already been not only appointed to undertake this duty, but having completed it. The answer is very obvious. Apart from the illegality of all the proceedings at the time the committee was formed—a point which it is not desirable now to discuss—it is the duty of any committee to report to the council, and the duty of the council to bring the matter in such manner as they deem best before the society for final decision.

## RENDERING ACTINIC NON-ACTINIC RAYS.

DR. VOGEL'S announcement a few months ago, to the effect that he had discovered a method of rendering bromide of silver sensitive alike to all the rays of the solar spectrum, was of a character so startling that experimentalists in various quarters of the world at once addressed themselves to a repetition of his experiments for the purpose of test and verification. In some instances we fear the test has been undertaken in a spirit of incredulity and antagonism; but in many others, it cannot be doubted, it has been undertaken in honest good faith, with a hope to verify rather than disprove. Unfortunately, it seems that in every instance recorded up to the present time the results have been negative. In no single instance have similar results been obtained. Dr. Van Monckhoven, in his paper brought before the Photographic Society on Tuesday evening, describes minutely his experiments, and his failure to obtain the slightest extension of the photographic image of the spectrum upon a bromide film saturated with the different aniline colours which Dr. Vogel had indicated, and also points out what he considers to be the failures in precision in the instruments used by Dr. Vogel, which have led to the error of deduction upon which the supposed theory rests.

As we shall publish Dr. Monckhoven's paper in our next, we do not enter into further details here; but we cannot help expressing a hope that notwithstanding the accumulation of negative evidence against the discovery, Dr. Vogel may yet be able to substantiate it. It is in perfect keeping with sound philosophy, and with the conviction of such sound philosophers as the late Sir John Herschel, that means should exist of extending the narrow limits within which at present actinic power is exercised by the solar spectrum; and the hope must rest in modification of, or addition to, our sensitive media. Dr. Vogel is challenged now to exhibit results, and we are not without a hope that he can and will do so. A print from one of his experimental negatives recently passed through our hands, and, so far as a brief examination permitted us to judge, an extended spectrum was undoubtedly obtained on the coloured film. The discovery is so important, and the discoverer at once so honest and capable, that we do not readily reject the alleged tangible proofs, even in the face of much negative result in the hands of other honest and able experimentalists.

## VISITS TO NOTEWORTHY STUDIOS.

### FRITZ LUCKHARDT'S STUDIO IN VIENNA.

WE are enabled to give our readers a glimpse of the studio of one of the most skilful and successful of Continental photographers, by extracting from one of Mr. E. L. Wilson's letters to his journal, giving details of his Continental ramble. Herr Luckhardt is not only a skilful photographer himself, but a cause of much good photography in others, as many of the novelties in style he has sent out have done much in stimulating photographers in other parts of the world. Mr. Wilson states that the studio did not impress him as so fine as many in America.

"It is situated on the roof or terrace of the Grand Hotel, and a long climb is necessary to reach it. But in Europe

people must get accustomed to such clambers, for it is a necessity; and in Mr. Luckhardt's case it seemed to make no difference, for his rooms were always crowded, and his camera constantly busy. His reception, dressing, exhibition, finishing, and delivery rooms are all on one floor, and over these the skylight, dark-room, printing, and solar camera departments are conveniently arranged, and supplied with every necessary thing to make the best of results. The assortment of furniture and backgrounds was lavish and elegant. The skylight proper was nothing extraordinary, but one in which the most beautiful effects are obtainable at almost all times. The drawings I annex will bring it more plainly to your mind.

"The first one is an exterior view: it represents it as standing on the ground, while in reality it is built upon the solid marble roof of a hotel, the other rooms mentioned being underneath in the hotel building. K is the entrance

from the roof to the dark room; B is the top light, which is sunk below the angle of the roof; D E and C are the side lights, both of which face the north. It reminded me more of Messrs. Trask and Bacon's Philadelphia light than any I have seen. M N is a 'sunshade' erected to protect the skylight from the southern sun. Separate from this on the roof are the printing and solar camera rooms.

The next figure gives us the exact ground-plan of the whole, and the third figure a sectional view of the skylight proper. The dimensions are given by the figures in Austrian feet and inches, and the Austrian foot is about three-eighths of an inch longer than ours. Where two commas are over the figure, it means inches, and where one only is used, feet are meant. I think it is plain to you without further description.

"Mr. Luckhardt usually works an open light, and from

both ends of the room, east and west. For cabinets and large heads he uses a four-inch diameter Voightlander lens, and exposes on an average about fifteen seconds. His card lenses are of the same excellent manufacture.

"We had many 'talks' together about photography and photographers, and I found him, as one must be sure of after examining his work, a man possessing first, the most exalted opinion of his art; second, the importance of making every picture as near as he can to perfection; and third, as full as he could be of that indescribable feeling which all must attain if they would excel. Works of art are scattered and hung all around, that he and his assistants may study them, obtaining an idea here and another there that will serve them at some time or another. For the same reason he subscribes for all the illustrated news-

papers, in order to study the pictures. He said, 'In the one I may find an idea for myself; in another something useful for my retouchers; and in all something of service to my printer, or pupil, or other assistants.' He truly said, 'The skylight construction is not the thing. It is the quality of the light from heaven itself. Give me that, and I will do all the rest, even without any studio. If the light is not good, I dismiss my sitter, and wait until it is good; or if they cannot wait, I ask them to come again. If they cannot do either, then I request them to go to another photographer, as I will not willingly make a bad picture. With me it is all a matter of feeling, and I cannot work without it. One cannot impart this to another, or hardly describe it. An expert will go over a number of examples of cloth, and tell you their value, but he cannot tell you how to do it.' It must be acquired by study and practice, and I guess once in awhile it comes naturally. Mr. Luckhardt examines and studies each negative carefully before dismissing the sitter, and if it is not up to his ideas, another trial is made."

FRENCH CORRESPONDENCE.

THE PARIS PHOTOGRAPHIC EXHIBITION—AWARDS TO ENGLISH EXHIBITORS—RODRIGUE'S PHOTO-LITHOGRAPHIC PROCESS—AFRICAN PHOTOGRAPHS—A NEW METHOD OF PHOTO ENGRAVING—MOOCK'S TREATISE OF PHOTOGRAPHIC PRINTING—SPIRIT PHOTOGRAPHS.

At the last meeting of the French Photographic Society, held on Friday, the 5th of June, a list was read of the awards which had been accorded to the photographers and manufacturers who have taken part in the exhibition now open at the Palais de l'Industrie. The number of medals and honourable mentions awarded, which are nearly equal to the number of exhibitors, tends to confirm what I said in my last letter regarding the exceptional excellence of this exhibition. The English artists who have sent specimens of their work have no reason to complain of the reception which has been accorded them, for, if I do not err, every one of them has received a medal or honourable mention. A *medaille d'honneur* has been accorded to M. Rousselon for his helio-engraving process.

At the same meeting, M. Davanne called the attention of photographers to the use of a wide-angle lens as a multiplying instrument, and he exhibited several impressions taken with it. A communication was also made describing the photo-lithographic process of M. Rodrigues (of Lisbon). This process, which is for the reproduction of line drawings (maps, plans, MSS., &c.), gives excellent results, and differs somewhat from the methods of Poitevin and Toovey, in respect to the paper which serves for obtaining the transfer being replaced by a sheet of tinfoil. It is upon this vehicle, spread upon a glass plate, that the film of bichromated gelatine is spread which is destined to be printed under the cliché.

The meeting was closed by M. Carotte, who presented to the society one of Weston's burnishers, of which a description appears in the PHOTOGRAPHIC NEWS of the 29th May. This simple and compact instrument, which gives a most agreeable glacé to the print, was extremely well received.

A great deal has been said about photography at the last two meetings of the Academy of Sciences. About a year ago, a Russian traveller, M. Schweinfurth, made known that he had discovered in Africa a race of dwarfs which he described as being the missing link between the man and the monkey. Recently, the Academy received some photographic portraits of two children belonging to this pigmy race, and who have been sent to Europe to be educated. Our savans have made a minute examination of these portraits, and in rectifying the erroneous details which have been given in the description, they have been able to establish the fact that these dwarfs are a variety of the negro race rather than a perfection of the monkey

race, and that one has here to do with an inferior order of men, and not with monkeys that have surpassed the limits which separate us from four-handed animals. The best sketches, and the most precise details, could make no way against photography, which, by reason of its fidelity, settled the question at once.

An expeditious and very economical engraving process has been brought forward for the preparation of maps and plans, which reminds one of the well known experiments made by MM. Donne, Fizeau, Claudet, and others, to transform the Daguerreotype into a printing block. The process was communicated to the Academy of Sciences on Monday last, and consists:

1. In covering a copper plate with a thin film of adherent silver upon which a coloured varnish is spread.
2. In drawing, with a dry point, any design, such as is done with a diamond in engraving upon stone.
3. Finally, in etching the tracing by means of perchloride of iron.

In the case of a reproduction, whether an enlargement or reduction, tracing may be dispensed with, by making a Daguerreotype impression upon the film of silver. The adherence of the silver yields a tracing, after etching, of great sharpness, a matter of much importance in the production of maps. The etching of perchloride of iron is very deep.

M. Leon Moock, who calls himself by the plain name of operator, has just published, under the title of "Complete Practical Treatise of Photographic Printing with Fatty Inks," a little volume which appears to us destined to vulgarise rapidly the new method towards which general attention has wandered during the last few years. He gives a resume of all that has been published hitherto, omitting such details as are not necessary in practice, and thus constituting his work a most correct manual. Notably, we find in one chapter, that treats of the development of the image, some details which appear to us of a perfectly novel character.

M. Moock has adopted copper plates as supports for printing, and it is upon this metal that he spreads his sensitive film and obtains his impression. To develop, he begins by treating it first with warm water, then with water of a much hotter description, which is changed three times every five minutes, and then the plate is plunged into a bath containing

Water	...	...	...	1000 cub. cents.
Galic acid	...	...	...	5 grammes
Gum	...	...	...	15 "

The plate is again washed, and dried. During the development in tepid water an accident may happen which at once causes the loss of the plate; for the gelatine not acted upon by light swells, sometimes, in a most exaggerated manner, under the action of the water, and then collapses. To prevent such a catastrophe, the film of gelatine should not be taken out of the water until it has been passed into the gallic acid mixture, and the temperature of the water should always be maintained evenly during the whole period of the development, and ought never to go beyond 35° Cent. In other words, great care must be taken to prevent the film of gelatine being exposed to the air between the two baths. The zinc bath employed should have a tap, by means of which it can be emptied gently. Before plunging the plate into the bath it should be rinsed with warm water, and as soon as it is to be changed the tap is opened, until half the water has run out, in such a way that the remainder is always sufficient to cover the film. The water that has escaped is replaced by other of a like temperature, and so on. The gallic acid solution, and the washings which terminate the operation, ought to be also warmed to a similar temperature.

Some time ago I heard mention made of spirit photographs, many of my friends having visited a photographer in Paris and had their portraits taken, in which they

appeared in company with a spectre whose shroud seemed almost to envelop them. They were always phantoms of illustrious persons, which was, naturally enough, very flattering to the models who shared the pose. Bertall, who is a humorous writer, an artist of talent, and a very skilful photographer, and a little credulous in matters of this kind, published in the *Petit Moniteur* an account of a certain séance in which he had been a spectator and actor, in company with an English chemist, at the photographer's in question. He seemed so sincerely convinced, not only of the supernatural character of the double portrait which had been made for him on this occasion, but of the marvellous skill of the operator, that I believed it was a question of some new invention, surpassing those which have been devised in America, in England, and in France, of late years. I made a visit to the photographer and medium, and, by chance, he happened to be away from home, and his wife received me. As I had given my name, she appeared very reserved, but at the same time showed me an album full of portraits of men, women, and children, each accompanied by the inevitable phantom. As a general rule, the spirit did not deign to show itself with face uncovered, and it was always a white figure of a vague and transparent character. Lamartine, Napoleon III., Alexandre Dumas, Rossini, Meyerbeer, Byron, and other celebrities of different countries were shown, enveloped in white mantles. I remarked upon the numerous and illustrious company which answered to the beck and call of the spirit photographer. "Ah, Monsieur," replied the lady, very flattered, "you see we have a large selection. . . ." I smiled at this avowal, and my informer bit her lips. She might have added that the collection could always be augmented by purchases from the Italian pedlars, who sell at reduced prices busts and statuettes of illustrious personages. Nothing looks so much like a spirit as a statue enveloped in a white cloth. As regards the method adopted for taking them without the client seeing the process, it is not, I think, necessary for me to say anything, for English photographers, no doubt, know many ways of performing the trick successfully. ERNEST LAGAN.

#### THE COLLODIO-CHLORIDE PROCESS.

BY W. T. BOVEY.

The few remaining members of that old school of photography who are keeping themselves strictly aloof from the wordy warfare now raging between parties, and continue to make it their study and pleasure to direct their best energies in advancing the interests of their favourite art, cannot but regard with feelings of regret the bitterness of antagonism and selfishness of design which are making rapid and disastrous inroads among a body of talented men who, at no distant period of the past, were wont to put forth their most vigorous efforts in the cause of progress, and who constantly vied with each other in giving publicity to their respective discoveries, applied improvements, comparative experiences, and, in addition to these, helpful advice to such as needed help. Most certain is it that I sincerely deplore those manifestations of splenic differences recently indulged in to the discredit of the actors, to the great hurt inflicted by such unwise quibbling on the future of photography; and truth bids me add my earnest protest against those applied attempts to set my name up as a handle wherewith to give a new turn of expression to the bitterness of personal jealousies or hate.

As regards the disputed question of priority connected with the addition of citric acid to a collodio-chloride admixture. As a matter of fact, I was the earliest worker in that particular; Mr. Swan followed directly afterwards; and Mr. Mayall took third place in making a similar suggestion. But as far as I am concerned, any person is welcome to the credit that falls to my share, inasmuch as I attach no greater degree of importance to such sugges-

tion than I should if, perchance, an experimentalist were to introduce a printing process in silver, that left for my suggestion the needed addition of a chloride to make the formula complete.

My first trial of the collodio-chloride process included an addition of citric acid, simply because prior knowledge of the principles of silver printing had taught me that chloride of silver alone is incapable of printing a vigorous image. I think it a matter deeply to be regretted that those gentlemen, who are now disputing over the matter of authorship, never questioned Mr. Wharton Simpson's claims immediately subsequent to his publication of a discovery, set forth unmistakably as his own in all particulars save the organic addition, which was first accredited to Mr. Swan, and subsequently to myself. Had any objections been made at the time of introduction, the whole matter might have been exhaustively discussed, and alleged priority of invention would thus have been easily and indisputably adjusted.\*

As far as the interests of photography are concerned, it matters but little to whom the credit should go, the process having been published by the author untrammelled with secrecy or other restrictions. The results it is capable of yielding are so beautiful that all the eulogies bestowed upon the process it richly deserves. That there are difficulties connected with the working I freely admit, but those are by no means insurmountable. I purpose, in my next, conveying some instruction which may, perhaps, enable experimentalists to overcome the chief difficulty of which they complain.

#### A FEW WORDS ON THE BEER AND ALBUMEN DRY PROCESS.

BY W. H. DAVIES.†

LOOKING over the pages of the YEAR-BOOK for 1874, an article by Captain Abney, R.E., attracted my attention, from the fact of yourselves and the journals having christened a similar process by my name. The gallant and scientific Captain seems to have been unaware of this, and that my first experiments must date back ten or twelve years, and that after it had been practised by a number of our members, and found to be good, Dr. Nicol brought it before this society in a paper published in the *British Journal*, July 26th, 1867, and thereafter described improvements on it in the "*British Journal Almanac*" for 1868. A curious coincidence took place with the publication of that paper, as with many other discoveries, improvements, and adaptations; the same journal (*B. J.*) which contained the paper read before this society, contained also a note by the editor, stating that a Mr. Murdoch (I think the name was) had forwarded for publication a process so similar that they might be called identical. Some of us thought this gentleman to be a mythical personage, invented by some sportive correspondent; but whether so or not, we have heard no more of him, and the albumen

\* So far as the question of fitness and decency is concerned, there can be no doubt that any question of authorship should be raised at the time a claim is made; but, so far as facilities for ascertaining the truth and adjustment are concerned, there are not more difficulties now than there ever were, as the whole question rests on published documentary evidence. In the year 1860 M. Gaudin made some experiments with emulsions of iodide and bromide of silver in collodion, and in one of his articles incidentally suggested that a similar use might be made of chloride of silver. None of the ingenious suggestions came into use, and were, we fear, for the most part forgotten. In 1864, in consequence of a conversation with Professor Iloscoe on actinometry, in which we pointed out the importance of an inert vehicle for chloride of silver used in such work as he had in hand, we resolved to try collodion. In a conversation with Mr. Spiller at the time, we mentioned this, and he expressed a conviction of its impossibility, and we neither of us had any remembrance or idea of any suggestion from M. Gaudin. We tried, and succeeded; and worked out a practical, successful process, in the course of which we produced the first collodio-chloride pictures we have any reason to believe ever existed. M. Gaudin, writing to us, and writing in his own journal, disavowed any claim, saying distinctly that on trying the suggestion he himself had made, he saw no possibility of success. The only challenge of our claim comes from the petty jealousy of a journalistic rival, and the motive is so transparent that it is really a work of absurd supererogation to expose it.—*Ed. PHOTO. NEWS.*

† Read before the Edinburgh Photographic Society.

beer process has, by general consent, been called Davies' dry process.

As practised by Captain Abney, however, its details are somewhat different, and I think somewhat more complicated. I have, however, gone over the process very carefully, to ascertain whether I could improve on my own system, and so be able to assist such of my fellow-workers who use this process regularly. In my hands, however, I am constrained to say that it does not come up in all respects to the old standard, although giving very good results—better by far, and surer, than many of the more vaunted dry processes. It is a peculiarity of every process into which albumen is introduced that it invariably improves the ordinary collodion negative.

Since the last publication of any words of mine on this process, I have made a number of little improvements which may be worth formulating and placing alongside Captain Abney's method, so that anyone wishing to practise a really serviceable and valuable dry process may have no difficulty in working one which has sufficient variability and elasticity to allow of such differences of detail as one ounce of albumen, or the white of one egg, to ten ounces of ale, as I use, up to the whites of four eggs or ounces, to half a glass or five ounces of beer, as Captain Abney uses. In working the process, all that is necessary to be insisted upon is, that a thoroughly porous collodion alone be used in this as in other dry processes, without which not one of them can be successful.

I will now quote shortly from the YEAR-BOOK the gallant Captain's method. After giving instructions as to sensitizing he says: "Immerse in a bath of distilled water till all greasiness disappears, and then wash for a minute or two under the tap. If distilled water be not at hand, use ordinary water (rendered slightly alkaline with potash, if iron be suspected as an impurity) which has previously been boiled, and filtered through charcoal; boil, filter through charcoal. If alkaline, add a drop or two of nitric acid, and use this for the first washing. Next, you must have at hand a glass of beer divided into two parts. To one must have been added one grain of pyrogallic acid to each ounce; the other must be plain. The whites of four eggs should have been beaten up carefully, and to each white, one fluid drachm of ammonia should have been first added. This is filtered through muslin, and placed in a bottle alongside the two beers. To a half ounce of the plain beer, half-an-ounce of the albumen must be added in a small glass, and the two mixed together with a rod. This is flowed on the plate, and allowed to rest on it half a minute. The mixture is then thrown away, and the plate thoroughly washed under the tap. A final wash of the beer containing the pyro is given, and the plate is then set up to dry spontaneously."

I now proceed to give my own method in detail as shortly as possible, consistently with stating clearly what is necessary:—First, albuminize the plate; secondly, collodionize; thirdly, bathe it the usual way as for any wet process, then wash under the tap or in dipping bath till greasiness disappears. Do not wash too thoroughly, as that tends to make the plates less sensitive; but if not washed enough, they turn brown—decompose, in fact. Well drain. The preservative is made of strong sweet ale, ten ounces or one half imperial pint, to which add from five to ten grains nitrate of silver dissolved in a few drops of water (or use an equivalent quantity of the bath you are using); stir with a glass rod, and allow it to settle, after which filter. More or less silver must be used as you find more or less of free chlorides in the beer, but always leaving a surplus of free silver, and shaking occasionally till the beer has taken up as much as possible of the silver, and, if necessary, refilter. Then, having taken the white of one egg (one ounce albumen) and twenty grains of gallic acid, add these to the beer in a forty-ounce bottle with a few pieces of broken glass in the bottom to assist in mechanically mixing the ingredients; shake rapidly and

thoroughly for a few minutes, then allow the whole to settle, and either decant or filter, as may be convenient.

To apply the preservative after washing and drying, run a small quantity over the plate and allow to run off, drain for a few seconds, run over a fresh coat, which will do for first coating the next plate, drain, and set up to dry. The more rapidly the plates are dried the better they are.

*Development.*—It is in the development, I believe, where there is any difference in many of the various methods of dry-plate work, and in this I think my present mode is superior to that used by Capt. Abney.

First, wet the plate all over; then, if there is any doubt as to over-exposure, use a plain solution of pyro of any strength from three to twenty grains per ounce of water; this may be left in a flat bath without examination for any time up to some hours. If fully out, wash and intensify as usual; if not, return to plain pyro for a longer time. But this is seldom needed, the alkaline method of developing answering admirably for this method, in using which I take the above plain pyro, and if the image does not begin to appear within half a minute, I add to it a few drops of a twelve-drop solution of ammonia fortis to one of water, and keep on adding till I arrive at the proper strength. No bromide of potassium is required, as the preservative itself is gradually washed into and mixes with the alkaline developer, acting as a restrainer of the more active ammonia.

Were it for nothing else but this one improvement, I would hold the beer and albumen preservative as the best of all the numerous family of that name, inasmuch as whatever simplifies a process without sacrificing any other essential, makes it at once more certain and desirable. Now this simplifies the method of alkaline development, and makes it as easy as the ordinary acid mode, a claim I have not seen made for any other preservative or method whatever. Another advantage is the power a few drops of the preservative gives of restraining the energy of the developer, whether that results from too much pyrogallie acid, too much ammonia, or too much exposure; and so, by judiciously arranging the developer to the exposure of the negative, securing a perfect picture, whether the plate may have had much or little exposure. After all, exposure is a merely comparative thing. A momentary impact of actinic force is quite enough if we can only hit on the developer by which that can be continued, intensified, and developed.

The same preservative may be used with bromide emulsion plates and with the purely bromized collodion bath plates, and with these it is in no respect inferior in most qualities to any other, and it has, in addition, the advantages I have claimed for it. If additional rapidity is needed, it is conferred by increasing the proportions of free silver and of gallic or pyrogallie acid, and cautiously reducing the strength of the beer-albumen with distilled water. I may mention that I use the gallic and pyrogallie acids indiscriminately; if one is not at hand I use the other. This must be borne in mind: the more rapid the prepared plates are, the more perfectly should they be shielded from the atmosphere, and the shorter time they should be kept between preparation and exposure.

Captain Abney mentions two months as the time during which he has found the plates to keep well. I have repeatedly used plates eighteen months old, and found them quite perfect; and to-night I lay before you a negative made from a plate prepared a year ago for Mr. Dallas, which you will see is quite perfect. A single fact I may mention as to the keeping after exposure. I find them to keep well for two or three weeks, but after that time the image seems gradually to become weaker, and after six weeks or two months, the image that remains is a mere phantom, incapable of being strengthened. My advice, therefore, is, with these plates, develop them as soon after exposure as possible, and in the interval between expo-

sure and development keep them free from dust and in a perfectly dry place.

And now a last word to those who have not yet determined on a suitable dry process, and to those dissatisfied with the one they are presently using. I say, unhesitatingly, try the process, and you will get first-rate plates, equal, in most respects, to wet plates, and superior in some; and as the proper methods of manipulation are mastered, you can calculate with absolute certainty on getting first-rate negatives.

## Correspondence.

### MAGIC LANTERN IMPEDIMENTA.—COLOURED GLASS.

DEAR SIR,—I hardly expected to have found it necessary to have another word or two with my friend Mr. Martin at present, but as, in "an educational work like the present," correctness in little matters is of vital importance, you will please give me room for a few lines in reply to his letter in last week's issue. He is still in a state of confusion as to what should be understood by pints and gallons, and rather uncharitably tries to arouse suspicion in the minds of simple folks as to the honesty of some of those with whom they have business relations. Let me assure them, however, that there is no cause for their apprehension. There is only one recognised legal pint by which buying and selling in our country can be carried on, and it measures twenty ounces of 437.5 grains. A gallon consists of eight such pints, and weighs, of course, exactly ten pounds; and equally of course, the fourteen gallons of Mr. Martin will weigh, not 112 lbs., as he still seems to think, but 140 lbs.

Regarding his notions on coloured glass, I am not at all sure that I understand them; yet my impression was, and still is, that he recommends two plates of yellow, and when the eye gets fatigued therewith, to give it a rest by letting green rays fall upon it; and this he proposes to do by slipping a blue plate between them. Now, although on the admixture of yellow and blue pigments an apparent green is produced, the same result is not produced by combining yellow and blue rays of light, either by the colour top or any of the other ways known to physicists, simply, as is known now, because green is a primary colour, and, along with red and violet, make up what we call white light. Of course, if my friend sticks to the old theory of red, yellow, and blue, I need say no more about it; but if he has advanced with the advance of knowledge, he must know that according to the modern theory, the light that passes through his pair of yellow plates is yellow, because compounded of red and green, and that the insertion of a blue glass cannot send an additional ray of green to rest the weary eye, but simply lowers the tone, and gives less to do. If Mr. Martin will spend half an hour in the examination of various coloured glasses with a prism, I am quite sure he will alter his opinion as to the double glass, and believe, with the great bulk of photographic mankind, that for ordinary bromo-iodized work a good orange, that absorbs all the violet, and transmits only the red and green (the former being slightly in excess), is best; and that if he wants to give the eye a rest with nature's glorious green, he will not do so by cutting off the red with a blue glass, but, for the necessary time, substitute for an orange, a plate of that refreshing colour; such, at least, is the opinion of your humble servant,

JOHN NICOL, PH.D.

Edinburgh, June 6th.

### PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

DEAR SIR,—In order to increase the funds of the "Photographers' Benevolent Association" the board of management propose to organize a distribution of photographic works of art, upon the principle of the art union.

To carry out this plan, will you kindly allow me to appeal, through your valuable pages, to professional and amateur photographers, for donations of photographs, large or small, singly or in quantity, mounted or unmounted. Parcels per post, or carrier, to be addressed to the Secretary, 174, Fleet Street, E.C.—I remain, dear sir, respectfully yours,

W. T. WILKINSON, Secretary.

PS.—As a beginning, Mr. England has kindly promised a liberal donation.

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

The last meeting of the present session was held in the Architectural Gallery, Conduit Street, Mr. J. SPILLER, F.C.S., in the chair. The minutes of a previous meeting were read and confirmed, and Mr. R. J. Friswell, F.C.S., was elected a member of the society.

Mr. DALLMEYER read a communication from Dr. Van Monckhoven on the sensibility of bromide of silver to non-actinic rays when saturated with a colour which absorbs those rays, describing experiments, testing and calling in question the theory of Dr. Vogel on the subject. Some negatives illustrating the subject were exhibited.

CAPTAIN ABNEY had tried some experiments, but failed to confirm the theory of Dr. Vogel.

After votes of thanks to Dr. Van Monckhoven and Mr. Dallmeyer,

The CHAIRMAN briefly described the purport of a paper by Mr. J. King, M.A., which, in the absence of the author, would be taken as read. The paper was devoted to a consideration of gelatine as a vehicle for silver salts, and described the method, in forming an emulsion of bromide of silver in gelatine, of removing the nitrate of potash and other soluble salts by means of dialysis.

Mr. KENNETT then read a paper on the gelatino-bromide emulsion process, and the use of a dry pellicle, in which he described his varied experiments and his method of forming the gelatino-bromide pellicle and keeping it in a dry state. Some examples of the pellicle and some negative transparencies and prints illustrating the value of the process were exhibited.

After a few remarks from the Chairman and a vote of thanks, Mr. Kennett, in reply to a question, said that the process of dialysis for removing surplus salts was practically useless.

Mr. HUGHES described some comparative experiments in the studio with plates prepared by Mr. Kennett. Wet collodion plates as usually worked for portraiture were tried with the gelatine plates with different relative exposures. The time required to produce a good negative with the dry plates was just the same as for similar results with a wet plate. He cautioned experimentalists against over-intensifying, as the olive tint of the gelatine plates was deceiving, the negative looking thin when it really had sufficient printing intensity.

A paper consisting of some notes on alkaline development, by Col. Stuart Wortley, was taken as read, and a vote of thanks to that gentleman was passed.

The CHAIRMAN, in adjourning the session until after the recess, said that the council had the subject of the revision of the rules under their attention, and he hoped shortly to make a communication to each member on the subject. The meeting would now stand adjourned until autumn.

After the adjournment, Mr. Hughes wished to know by what authority the council were revising the rules, a committee having already done that work? Dr. Mann pointed out that the real object desired was a revision of the rules, and the committee had only sent in a draft for consideration. That draft, or a draft by the council, or both, could only be decided by the members at large. Some conversation followed, in which anything like factious opposition was deprecated as unwise and injurious.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

The eighth ordinary meeting of this society was held in the Bible Society's Rooms on the evening of Wednesday, the 3rd inst., the president, Mr. R. G. MUIR, in the chair. The minutes of the last meeting were read and approved, and the following gentlemen were admitted ordinary members:—Messrs. John Lessels, Grierson G. Mitchell, and John Murray Gartshore.

The CHAIRMAN said that before proceeding to the ordinary business of the evening he had to intimate the presentation to the society of two very handsome gifts—an oak book-case by Mr. Murray Gartshore, and a fine copy of Rejlander's "Two Ways of Life," by the family of their late fellow-member, Mr. James Wood. Some three weeks ago, on the invitation of Mr. Gartshore, he and the two secretaries had visited Ravelston, and spent a very pleasant day in examining the house and grounds. As one of the out-door meetings was intended to be held there, the members would see that it was a perfect mine of photographic wealth. In one of the rooms Mr. Gartshore showed them the book-case, which, in consequence of alterations, had been removed from the library, and kindly offered it to the society, if it would be of any use to the

members. They of course gladly accepted the offer, and he might add, that in addition to its intrinsic value, it was said to have the still higher merit of having been designed by Sir Walter Scott.

Mr. DAVIES said that no more acceptable gift could have been received, as the members were aware that the committee had been for the past two or three years looking out for a suitable book-case in which to keep the literary and artistic property of the society. He moved a very hearty vote of thanks to the liberal donor of the useful gift. Mr. W. NELSON seconded the motion, and requested the secretary to convey their thanks to Mr. Gartshore.

Mr. TUNNY, in proposing that the thanks of the society be conveyed to the family of the late Mr. Wood, said that he was glad that the society now possessed a copy of Rejlander's interesting picture. It was the first, and, perhaps, most successful, attempt at combination printing, and excited much interest and discussion at the time of its publication. This was seconded by Mr. WANSHOPE, and the secretary was requested to get it suitably framed, with a view to its preservation.

The PRESIDENT then said that the business committee had for some time been anxious that some member should undertake to bring before each meeting a short paper, consisting of brief gleanings from the photographic journals, with as brief comments or criticisms—the spirit of the journals, in point of fact—but they had not till now succeeded in inducing any one to undertake the duty. Mr. Davies, however, had consented to make a beginning, and would now read the first paper (see page 278.)

Mr. TUNNY, in reference to Mr. Davies' observation regarding Obernetter's process for the reproduction of negatives, said that Mr. Carey Lea seemed in high dudgeon with M. Obernetter for claiming to be the originator of the process, and said that it was nothing more than a modification of one previously published by him. If that be so, then, most assuredly, Mr. Lea could not claim originality in the publication, as his was nothing more than a modification of that published by Camarsac, and one patented by Jonbert at least fourteen years previous. He himself had been working in the same direction as early as 1855, and had got fair results by adding bichromate of potash to a mixture of dextrine and albumen, exposing under a negative or positive, and brushing on the lampblack or carbon (got by holding a piece of glass over a burning candle).

Mr. DAVIES said that photographic inventors and experimenters should be diligent readers of the journals, else they would most certainly be constantly getting into hot water. He had no doubt that many unsound claims were made in ignorance of what had been done before, but he was equally sure that many were made in connection with which charitable supposition would be thrown away. As a case in point, he might mention the manufacturer of (he thought) the only commercial steam coagulated albumenized paper, Mr. Skinner, late of Glasgow, now of London. He had come to Edinburgh, called on him (Mr. Davies), and had been introduced to Mr. Wood, the discoverer of the method. From both he got all necessary information, and then went off to the proper office and registered it, which was, of course, not worth the paper on which it was written, much less the fees which had been paid.

Mr. PRINGLE said they had got one of the nine-inch rotary burnishers, which at first seemed as if it would do; but, although he was not yet in a position altogether to condemn it, they were not certainly pleased with its work. In the first place, they had discovered on the burnisher a scratch so minute that it required the aid of a lens to see it, and yet it made its mark on every print; and the agent through whom it was sent refused to exchange it, on the ground that they were all tried and found right before being sent out. This, of course, would show how much care would be required to prevent a speck of hard dust getting between the print and the burnisher. Then he thought the roller was much too small for the size of the plate, and in consequence—in their hands, at least—the polished surface of the print was covered with wavy markings running at right angles to the way in which the burnisher had passed over it, as would be seen in the card which he laid on the table. And lastly, when the light was applied to heat the plate, there was a large quantity of condensed moisture formed, which caused considerable delay before getting to work, and which would tend much to oxidize or rust the polished surface of the metal.

Mr. TURNBULL had tried one of the burnishers thoroughly, and did not like it. It was more difficult and troublesome to work, and did not produce a better, if as good, surface as some of the older presses in the market. The machine was simply cast iron, and the prices charged were ridiculously high.

Mr. TUNNY heartily agreed with all that had been said against the burisher, and begged to say, in addition, that it pulled the paper in such a way as to produce absurd distortion.

Mr. DAVIES then read a paper entitled "A Few Remarks on Dry Plates, with special reference to Captain Abney's Beer Process" (see page 285), and laid on the table a number of fine negatives to show what the process, as worked by him, was capable of producing.

They were much admired, and several members said that their experience led them to consider Davies' process the best yet introduced. Dr. Thompson had wrought it successfully for a long time, and he had also tried putting the plate direct into the beer preservative, with considerable advantage.

Mr. W. NEILSON, in moving a vote of thanks to Mr. Davies, said that he had done the "Spirit of the Journals" so well, that he ought to continue it, and he was certain that such monthly papers would elicit much valuable information. The vote was carried by acclamation.

Two questions from the box—"What are the relative advantages of alkaline and acid pyrogallic development?"—and "What is the most likely cause, and best remedy, for the blistering of albumenized paper?" were deferred till next meeting.

#### OLDHAM PHOTOGRAPHIC SOCIETY.

A SPECIAL meeting of the Oldham Photographic Society was held on Tuesday evening, June 2nd, for the purpose of selecting a presentation print, and fixing a time and place for the out-door meeting.

A number of prints, sent by V. Blanchard, were laid on the table by the secretary, and so excellent were they thought by the members, that they resolved to retain for their portfolios all prints not selected as presentation prints.

The out-door meeting was fixed for Alderley, on June 11th.

### Talk in the Studio.

HARVEY and REYNOLDS' HEAD-REST.—We have been favoured with photographs of a new head-rest, recently introduced by Harvey and Reynolds, which seems to possess especial points of efficiency and convenience, besides a broad and firm base, giving steadiness; easy facilities for moving; and support alike for head and body. There appear to be admirable contrivances for adjusting these rests to any position of the body, and a capital plan for throwing the support out of the upright, to bring the rests into convenient position, which will often prove of singular value in adjusting the rest for use in groups, as well as for ordinary standing and sitting figures. So far as we can judge from the pictorial presentment, the new rest seems to be in every way capital.

TETSCH v. THOMPSON.—A case possessing some curious interest to photographers, which has been pending nine months, was decided in the Court of Exchequer on Thursday, before Mr. Chief Baron Pollock. Our readers will remember that during last year Mr. Thompson charged an operator of the name of Tetsch, at Bow Street, with stealing certain negatives, but subsequently withdrew the charge on restoration of the negatives. Subsequently the accused brought an action for slander against Mr. Thompson, based upon this charge. After various delays, the case came for hearing on Thursday, Mr. Arthur Cohen, Q.C., Mr. J. C. Matthew, and Mr. Murphy, being instructed for the defence; Mr. Campbell White appearing for the plaintiff. During the examination of the plaintiff, the Chief Baron remarked that after the decision at Bow Street no action could lie, and recommended the withdrawal of a juror; and this course being adopted, the case came to an end without a verdict.

PHOTOGRAPHIC IRRADIATION.—In the course of some recent correspondence Mr. Stillman, writing in *Nature*, referred to the notion that photographic irradiation was due to reflection from the back of the plate, and mentioned backing and colouring the film as remedies. He added:—"But the most complete (where the dry emulsion process is available) is to allow the collodion to be acted on by a large excess of nitrate of silver for a considerable time, and then to convert this into bromide of silver by addition of ammonium bromide. The result is that the film has a dull opaque character, like unglazed porcelain, and not only stops the light more completely than an ordinary collodion film, but remedies another cause of irradiation—the molecular reflection in the film itself." Lord Lindsay and Mr. A. Cowper Ranyard, writing in response, point out that reflection from the back of the plate is not the sole cause of this defect. They remark:—"When an over-exposed photo-

graph is taken upon an opaque plate a marked fringe of irradiation still remains, and experiments were instituted by us which appeared to show that this is not to be accounted for by any circulation taking place within the thickness of the collodion, or by the chromatic dispersion of the lenses; but when the oblique pencils from the edges of the lenses were stopped out the irradiation fringe was found to be greatly decreased. We were led to conclude that irradiation is to be accounted for by the fact that each luminous point in the object is not accurately represented by a luminous point in the image, but rather by a luminous patch of sensible area, the central and more intense portion of which prints itself first in the photograph, giving comparatively sharp picture prints when the exposure is short; but as the picture is still further exposed, the outer portions of the luminous patches imprint themselves, and by their overlapping cause the blurred appearance to which has been given the name of irradiation."

### To Correspondents.

STUDIO.—We should prefer No. 3, which, as you say, approximates to the model of Mr. Fry. The nearer to north you let it face the better, but north-east will do. 2. We have had no experience with the lens in question.

A SUBSCRIBER FROM THE BEGINNING.—It very often happens that a person not absolutely familiar with every detail of photographic history discovers something which he, in good faith, believes to be original. He hastens to the Patent Office, and enters a provisional specification; but, on discovering that the thing is not new, takes no further steps. This was probably the case in the instance to which you refer.

MARKINGS ON THE PLATE.—The peculiar, irregular markings, of which you send examples, are at times very troublesome, and the cause is not well ascertained. They generally occur with an old bath, and sometimes with a doctored bath. But it is not by any means certain that the condition of the collodion is not conducive for diluting the collodion with alcohol or with thin plain collodion is often found to be remedial. Allow the plate to set well before immersion in the bath, and keep it in motion laterally as soon as immersed. These steps sometimes cure, and generally mend the matter somewhat.

W. R.—You should have described the method by which the transfer was produced, and we could then with more certainty have suggested the cause of the defect. Its probable cause is imperfect washing, some traces of hyposulphite having been left on the film, and this, and probably the action of the toning bath upon it, have caused the discolouration.

A. R. (Hunslet).—The best method of enlarging consists in producing a transparency and an enlarged negative by one of the various methods we have recently described. Many articles were devoted to this subject in our last volume. It would be impossible in this column to give details, and we cannot possibly write private letters on such subjects.

ONE WHO WISHES TO KNOW.—We regret that our information on the subject is insufficient to enable us to give efficient advice. How far a photographic assistant would have a chance of an engagement at all in Japan we cannot say. In the United States there are doubtless many openings; but whether more or better than in this country we cannot say. The same is true of most of the colonies: salaries are probably higher than in this country, but so also are expenses.

NOVITIUS.—We cannot speak from comparative trial; but we should give the preference to No. 2.

FERD. W. GER.—The matt silver stains are chiefly due to the use of a horny, repellent collodion; but other conditions will conduce. If you cannot readily change your collodion, adding a few drops of distilled water to that you are using will improve matters. Immersing the plate before it is too thoroughly set will help you. Placing the plate always on clean pieces of blotting-paper, and frequent washing of the inner frames, will help you.

C. KEENS.—Dr. Monckhoven's "Traité General de Photographie" is published by Masson in Paris, we believe, and may doubtless be obtained through a foreign bookseller. We do not remember the price, but we should think about 15s. A new edition was published last year. A letter addressed to the author, Dr. Van Monckhoven, at Ghent, would doubtless secure you all information.

P. B. C.—We know of no toning bath better suited for giving such warm tones than the acetate bath, containing one grain of chloride of gold, thirty grains of acetate of soda, and five ounces of water. Vigorous negatives form an important element in producing such tones. You cannot secure rich, vigorous prints with fine tones from a poor, flat, foggy negative.

AN OLD SUBSCRIBER wishes to know to whom he should apply for permission to photograph in the enclosure at the camp at Wimbledon. Can any of our readers give the information?

W. C.—Writo to Marion and Co., 23, Soho Square.

Several Correspondents in our next.

## The Photographic News, June 19, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PHOTOGRAPHY AND BANK NOTES—THE CAMERA IN ENGINEERING—COST OF ALBUMENIZED PAPER.

*Photography and Bank Notes.*—M. Gobert, whose name is known as one of the most active members of the Photographic Society of France, has been visiting this country for the purpose of studying methods of photographic printing other than that of silver employed here. His chief object is to ascertain how far printing with greasy ink has advanced in England, and whether there are any modifications or improvements made use of in England which have not found their way to the Continent. M. Gobert speaks most sanguinely of the state of mechanical printing in Paris, and is very hopeful indeed of comparative perfection in the art being obtained in a little while, in proof of which he cited the fine examples of heliographic printing now being shown at the Photographic Exhibition at Paris. M. Alfred Gobert is an official of the *Banque de France*, which has lately established a photographic studio in connection with its works, and especially as an aid in the detection of spurious bank notes. The camera, it appears, is a much more rigid detector than the human eye, and consequently the photographer's lens is at times put to a use akin to that of a policeman's bull's-eye. Thus, in the case of an erasure on the paper of a bank note, and the substitution thereon, either by printing or writing, of some word or another, although sometimes quite invisible to the eye, this is at once laid bare in a photograph, the lack of reflection, or otherwise, being quite sufficient to make a mark upon the collodion film, which carries at times, too, the outline of the word that has been erased. Photo-mechanical printing is an art, too, which the great Paris Bank proposes to make use of in the printing of their notes, for the progress made of late years in this branch of photography seems to prove that it may be employed with advantage in this connection. In many Continental bank notes, and notably those of Germany, it is the custom to print at the margins, with type of the very, very finest character, a warning to the effect that any one attempting forgery is liable to penal servitude for twenty years; the microscopic nature of the printing being supposed to be the most efficient guard against committing such a crime. In these days, however, of photo-mechanical printing, the production of characters of this minute size would be by no means the most difficult portion of the task to perform in the forgery of bank notes.

*The Camera in Engineering.*—It is really surprising to find how widely photography is employed by engineers now-a-days in taking pictures of new machines and machinery constructed by them. The first step taken by large firms, after constructing a model, is to have it photographed; and so we find large factories, such as Armstrong's, Whitworth's, Nasmyth's, and the like, giving the photographer continual work. At Krupp's factory at Essen, the biggest in the world, probably, where all the German steel artillery and many of the Russian guns are manufactured, there is not only a photographer's studio attached, but work carried on to such an extent as to permit of mechanical printing being adopted, the Albertype process being employed for printing the pictures. Photography used in this way, although it does not do away with draughtsman's work, at any rate lessens the amount of this more costly labour, for in many cases when pictures are taken to scale, the photographs are quite as good for purposes of guidance as a working drawing. There are other instances, again, where photography does what the draughtsman cannot do—where it shows, for instance, the machine complete, and the manner of putting it together—and all this it does in a small fraction of the time required for a rough sketch to be pencilled out. We do not know

whether the suggestion made some time ago to print duplicates of tracings direct through the paper, instead of producing them by hand, is adopted, practically, by any firms; but one would think that, with paper already sensitized at one's disposal, with but the simple operations of fixing and washing to be performed, engineers and draughtsmen would be only too ready to adopt such a rapid and trustworthy manner of copying their drawings and plans.

*Cost of Albumenized Paper.*—The high price of paper, which has of late been yearly increasing, will be felt, we fear, very seriously by photographers who are large consumers of albumenized paper. Unfortunately, the manufacture of their raw paper is in the hands of two or three large firms who have practically a monopoly in the matter. In Vienna, as also in Berlin, an increase in the cost of the paper, as also other circumstances, have caused photographic dealers to advertise an increase of as much as twenty-five per cent. in the price of the albumenized material. The movement seems a very decisive one, and has not been undertaken until after much deliberation, the Berlin dealers actually agreeing among themselves before making the bad news public. As many as eleven large firms have stated their inability to supply albumenized papers to their customers except at the advance of price above mentioned, the well known names of Schippang, Beyrich, Kleffel, and others being among them.

### ON AN IMPROVED DRY PROCESS.

BY M. CAREY LEA.\*

In reflecting over this process, it occurred to me that silver nitrate was so completely precipitated by albumen that there could be no reason or advantage in this preliminary washing; that, on the contrary, it was probable that a better result would be got by plunging the plate directly into the albumen bath as soon as set.

The importance of this change seemed so great that I first experimented with it in the following manner. An emulsion was taken with a very large excess of silver nitrate, an excess of ten or twelve grains to the ounce. This large excess was to make the trial more decisive, and for the same reason the plate was coated twice, so as to get a very thick film with a large quantity of silver nitrate. A solution of albumen was prepared, which, to increase the severity of the trial, was made very dilute, one per cent. only of albumen dissolved in water, half a drachm of albumen to six ounces water. Into this the plate was plunged as soon as set. It was taken out when the greasy lines had disappeared, and the bath was tested for silver nitrate. None had been removed from the plate, and this was also the case (or only the very faintest infinitesimal trace) when the plate had been left in some time longer. All the silver had been converted into silver albuminate within the film, so that evidently the previous washing as always hitherto practised could be dispensed with advantageously, at least with an albumen preservative, because in this way a larger quantity of organic insoluble silver salt was retained inside the film. The above trial was made by daylight.

Experiment with plates prepared in the dark, and exposed in the camera, gave the fullest confirmation of the expectations I had formed: in fact, the gain was much greater than I had ventured to hope.

So that now I conclude that when albumen is used, the washing of the plate is just as injurious and unnecessary as would be the washing of an ordinary wet plate before plunging it into the silver bath. The wet and dry processes are thus brought curiously together, for in both the plate is collodionized, and then simply plunged into a bath, and is then finished. The albumen plate may be either dried or used wet; when wet it is even more sensitive than when dry.

The simplification obtained in this way is sufficiently evident, and the diminished trouble in making the plates, also the difficulty about pure water for the washing. But these considerations are very unimportant compared with the gain to the plate itself. The advantages are:—

1. It is much more sensitive. With an equal exposure the development is over in one-fourth the time, and with one-fourth as much ammonia carbonate.

2. The irradiation and blurring are greatly diminished. Small dark objects projected against a bright sky are depicted clean and sharp. Small leafless twigs in deep shadows standing against a bright sky, instead of having an indistinct and blurred effect, come out as sharp as if they had been cut in the film with an engraving tool.

3. There is better detail in the deep shadows, and more variety of half tone.

4. Much less tendency to spots and pinholes.

I shall now proceed to give the formulæ. Besides the introduction of albumen to the emulsion process, and the change respecting the washing, I have found several other improvements which promise to be valuable. I find an advantage in adding cobalt chloride to the collodion, and an alkaline nitrite. These two changes are of less importance than those previously mentioned. They are not essential, and may be omitted, but they have their utility, and I prefer to employ them. Another change of more importance is the following. In processes in which albumen has been used, it has hitherto taken the place of other preservatives. I use it in connection with them—that is, with gallie, pyrogallie acid, gum, &c.

#### COLLODION.

Dry cadmium bromide ...	200 grains
Ammonium bromide ...	48 "
Pyroxyline ...	240 "
Ether ...	20 fluid ounces
Aleohol ...	12 "

To this may be added with advantage:—

Cobalt chloride ...	32 grains
Potash nitrite ...	32 "

Potash nitrite dissolves with some difficulty in aleohol. Half the twelve ounces of aleohol should be appropriated to dissolve the nitrate, the other salts to be dissolved in the other half. Keep the collodion in a warm light place for a month. Without the right sort of cotton a total failure will result, or at least only a partial success. The best pyroxyline I have had was made for me.

When it is intended to prepare an emulsion, three or four ounces of collodion are taken, and to each ounce two drops of aqua regia are added. (Aqua regia is easily prepared by adding half an ounce of nitric acid to an ounce of hydrochloric in a stoppered vial, and setting in hot water until the mixture turns orange colour.)

The silver nitrate in fine powder is weighed out, taking twenty-three grains to each ounce of collodion (if the cobalt chloride and potash nitrite are used, then twenty-five grains silver nitrate). This is dissolved in aleohol. To do this take a large test-tube capable of holding about three ounces, so that the aleohol may occupy but a small space at the bottom, and be in no danger of boiling over. Cover the powdered nitrate with aleohol about an inch deep. Boil over a gas flame, shake, boil again, and after a couple of minutes, pour this into the bottle of collodion, and instantly shake well for a couple of minutes. Pour a rather less quantity of aleohol over the residue in the test-tube, and repeat. The third time ought to finish the solution, but if not a fourth may follow. The shaking is much more effective if a bottle of such size be selected that is only about one-third filled. Of course it must be wrapped in opaque yellow paper.

After about ten or twelve hours it will be ready for use. In the middle of this interval it should have one more good shaking. Just before using it should be filtered through sponge or fine close linen. The plates should be

edged with india-rubber dissolved in benzole, the edging along the sides not quite meeting that at the ends, but leaving an opening for the escape of water under the film. To get an even coat, pour on plenty, carry it over the plate quickly, and in rocking raise the far end but little, and slowly. These three rules will be found very useful.

As soon as set, plunge directly into the preservative bath.

#### Preservative Bath.

Water ...	8 ounces
Gum and sugar solution ...	10 drachms
Prepared albumen ...	5 "
60-grain solution of gallic acid in alcohol ...	3 "
60-grain solution of tannin in water	3 "

The tannin may be used, or left out. The ingredients must be added in the above order, or a flocky precipitate may be produced, which ruins the bath, even if filtered out.

*Gum-sugar Solution.*—Dissolve half a pound of good gum arabic and three ounces of white lump sugar in forty-four ounces of water. Add one and one-half fluid drachm of carbolic acid to make it keep. Shake well, and filter.

*Prepared Albumen.*—To the whites of five eggs add an equal bulk of water, and a quarter-ounce of acetic acid No. 8. Shake well, and filter through sponge.

*Backing.*—It is best to back the plates. Take one quarter-pound annatto, three ounces water, one quarter-ounce glycerine, one half-draehm carbolic acid. It will take about two days for the annatto to soften in the water, and mix up to a thick paste, to be applied with a brush. If the paste, by standing, dries too thick for use, add water, but no more glycerine.

*Development.*—For a whole size plate, take a 7 by 9 pan, put in four ounces of water, and half a draehm of sixty-grain aleoholic solution of pyrogallie acid. Put the plate in (having previously removed the backing by sponging), leave it for a minute, then take it out, and put into the pan one half-draehm of a fifteen-grain solution of potassium bromide, and half a draehm of eighty-grain solution of flinty (not powdery) ammonium carbonate. If the exposure has been sufficient, this will presently bring up to printing density; if not, add a little more carbonate. If any trouble is experienced in getting density, it is better to re-develop with citric acid and silver, either before or after fixing. If the image is very faint, re-develop as before; but a weak image indicates bad materials, or some mismanagement.

*Fixing.*—Very weak hyposulphite, one ounce to the gallon.

The negatives obtained by this process are not only excellent in quality, but very attractive in appearance—much more so than ordinary dry plate negatives. In actual practice, the process is very easy and pleasant to work.

### ON THE GELATINO-BROMIDE PROCESS, WITH A DESCRIPTION OF AN EASY METHOD OF WORKING IT BY USING THE "SENSITIVE PELLICLE."

BY R. KENNETT.\*

THE general subject of "gelatine as a vehicle for silver salts in the production of negatives" having been introduced by Mr. King's interesting paper, I propose to follow up the subject by describing the method that I employ. I may mention that the use of gelatine as a substitute for collodion is a matter to which I gave serious attention many years ago. I have always been interested in experimental photography, my first commencement being with Daguerreotype nearly thirty years since. I have taken interest in, and have worked at nearly all the various pro-

\* Read before the Photographic Society of London.

cesses that have arisen since that time, always as an amateur. Among other of the old methods of preparing dry plates, that of Dr. Hill Norris particularly interested me. I was convinced that most of their excellent qualities, and especially that of their certainty, and the long retention of their sensitiveness, were due to the final coating they received of gelatine. I thought that if this material played so important a part, why could not the collodion be dispensed with, and gelatine be used exclusively? I was an early worker in Major Russell's tannin process, and when he took to using a bromide process exclusively I tried his method, but I used gelatine only, and I formed the bromide of silver in an emulsion of this material, much as we now do. I also added iodides and chlorides to the bromides: I used the acid pyro developer at first, but I finally settled down to the alkaline method when Major Russell showed its superiority. Of course I had no end of failures in trying to work out a process in this new direction; but a serious illness of six years' duration stopped all my photographic experiments. As a worker, therefore, in gelatine, I do not appear as a novice, but rather as a veteran.

My interest in the subject was revived about this time last year, when Mr. Burgess, of Peckham, announced the sale of his gelatino-bromide emulsion. I obtained some of it, and I immediately recognized a similar preparation to that I used to make some years previously.

On referring to my old note-book in which my experiments were recorded, I found a formula by which a sensitive emulsion could be made similar to Mr. Burgess's. I showed the preparation and negatives obtained with it to Mr. J. T. Taylor, and promised to publish the formula. As Mr. Burgess was then deriving some benefit from the sale of his emulsion, I did not then, in deference to his wish, publish my method. I thought also I might make some further improvement in the only weak part of the process, the preparation of the emulsion, so as to enable it to have keeping properties.

Since then I have followed up my experiments, and although I have not discovered a method of preventing the prepared sensitive emulsion from spontaneous decomposition, yet I believe I have done something better; for I have discovered a means of preparing the gelatine so that in a dry state it shall contain the sensitive salt. The material can therefore be purchased in a state ready for use by dissolving in warm water; and in this dry state it will keep good for years. My object in this paper, then, is not only to show that the gelatino-bromide process is a really good working process, but also to prove that the only troublesome part about it—the preparation of the emulsion—may be avoided by obtaining, as an article of commerce, the material ready for use. In former times it was the custom, much more than it is now, for photographers to prepare their own chemical compounds. It is now found that these things can be better done by people who make it their special occupation; hence photographers now rarely prepare their own collodion, make their varnishes, albumenize or salt their papers. Such being the case, I do not believe that it is sufficient to merely describe how the materials are to be prepared, in order to get a new process into general use.

Different methods have been published by Dr. Maddox, Mr. King, Mr. Bolton, and others, of forming a gelatino-emulsion. It is not so difficult to make as a collodio-emulsion, as all the solutions are aqueous ones; yet it requires care. Any good gelatine will probably do; but my experience is with Nelson's, which answers admirably.

I take one pound of this gelatine and place it in a porcelain dish, to which I add 100 ounces of distilled water, and allow it to stand and swell for about three hours. It is then heated by a hot-water bath until dissolved. While hot, 8½ ounces of bromide of potassium are next added, which must be thoroughly incorporated with the gelatine by stirring, and 11¼ ounces of nitrate of silver,

dissolved in as little water as will take it up, are then added, and the whole well mixed while the gelatine is still hot.

When the silver is added, all the subsequent operations must be done in a non-actinic light; and the material thus formed constitutes the sensitive emulsion. It is not, however, in a condition ready for use, as it contains free bromide of potassium and the nitrate of potash formed by double decomposition. These salts must be removed, or else they will form crystals in the film, and spoil the plate. Mr. King removes these salts by the scientific process of *dialysis*; I proceed in a different way. I pour the emulsion into a porcelain dish to the depth of about a quarter of an inch, and let it become cold and set. I then cut it into small strips, and wash in many changes of water, or use running water, just like washing prints from the hypo, until all the free bromide and nitrate of potash are dissolved out. The material is now in the condition to be dissolved in hot water ready to coat plates with; and if no greater quantity is made than can be conveniently used at one time, the plates can at once be prepared and the emulsion used up; but unless the material can be so used immediately, it cannot be depended on. I have sometimes, in cold weather, been able to keep it good for a fortnight, and in summer time I have known it to decompose in a few hours. It is true that many things may be added—such as carbolic acid or alcohol—to arrest the tendency to decomposition, but in my experience there are other drawbacks which accompany these additions, and my decided impression is, that no such attempt should be made, but that the emulsion should be at once used by coating the plates, and then, when dry, the plates will keep good for years.

To obviate the necessity of thus immediately using up the prepared emulsion, my invention comes in. I take the concentrated emulsion, after it has been well washed from the removable salts, and place it in suitable dishes, evaporating the emulsion till it is of the consistency of thick paste. I then let it cool, and, removing it from the vessels, complete the drying on suitable frames. When dry, it can be cut into portions of convenient size, and in this condition is ready for immediate use by simply dissolving in hot water. As much or as little may be dissolved at one time as there are plates to be prepared; but as the plates will "keep" indefinitely, there is no need that any should be lost, if sufficient plates be ready to use up the dissolved material.

This dried sensitive material I have called my "sensitive pellicle."

To use the "pellicle," the quantity necessary to coat the number of plates proposed to be used is dissolved in the proper quantity of water according to the directions that accompany each packet. When thus dissolved, the emulsion is in exactly the condition as if the person had originally made the preparation himself. All the subsequent operations are just the same as are given by Mr. King and other workers of the process.

My mode of working is this: I slightly warm the plate, pour enough of the warm emulsion to make a pool in the centre of the plate, and with a glass rod guide the material to the edges, pouring the surplus back. The plate is then placed on a level surface—a shelf, for instance—to dry. If prepared at night, the film will spontaneously dry by the next morning.

You will observe that there is no preliminary coating of the plate required, no after washing necessary, and no "organifier" or preservative solution to be floated on, or washed off. The gelatine is its own "organifier," and the plates will keep indefinitely if preserved from light and moisture.

The exposure required is certainly not more than for the most sensitive wet collodion. Nearly all the failures from the use of this material that have come to my knowledge have arisen from an under-estimate of this sensitiveness.

They have been from either too much light in the dark room, or from over-exposure in the camera.

After exposure the plate is soaked in water for a short time, and the usual alkaline developer is applied; the image comes out quite as quickly as on an ordinary wet plate. Sometimes a little intensifying is necessary; this may be done before or after fixing in the hypo. The greatest care is necessary not to carry the intensifying too far, as the colour of the deposit is so much more non-actinic than collodion negatives. After washing from the hypo the film dries spontaneously in about the same time as a collodion one; but heat may be used to hasten the drying. When dry, the film is sufficiently hard that the negative may be printed from without varnishing. If the negatives be intensified too much, the surplus intensity can easily be removed, and if not intense enough, fresh vigour can as easily be added.

In conclusion, and before I commence my demonstration, let me urgently call on you to give this gelatino-bromide process a fair trial—whether you use my pellicle, or prepare the emulsion for yourselves.

I believe it to be the easiest, the quickest, the cheapest, and the least destructive to the health of all the various means by which negatives can be produced. The general process is free from all restraint; the only part I claim for myself is my own invention—the drying of the emulsion, and the capacity of thus keeping it in a dry state ready for immediate use.

#### A FEW NOTES ON ALKALINE DEVELOPMENT.

BY COL. STUART WORTLEY.\*

I HAD intended, when offering to read a paper on the above subject to the society, to have developed a series of negatives and transparencies before you at the time of reading the paper; but as there are already two papers that have precedence of mine, I fear that time would not allow of my doing so this evening. There is one point in particular to which I desire to call the attention of dry-plate workers, as I find from various communications that I have received that it is one that has not hitherto been sufficiently considered.

It will be remembered that last year I brought out the strong alkaline developer, and ventured to point out that the photographic world had, in confining themselves, as they had hitherto done, to a very weak alkaline developer, sacrificed at least three-fourths of the sensitiveness of any dry plates that they have may be happening to use.

My friend Mr. R. M. Gordon was so struck by the results obtained by me that he at once adopted my method of developing, and has published his testimony to its value; and I believe that all dry-plate workers who have given the subject their attention have also adopted the strong developer in their work.

Now I find that dry-plate workers, whether using a weak or a strong alkaline developer, have not given sufficient consideration to the fact that where a negative requires an extra dose or two of ammonia to bring it out, it is most desirable, if not indeed necessary, that a drop or two of strong pyrogallic acid solution should be added with each addition of ammonia. The reason of this would appear to be that the original amount of pyrogallic acid used with the developer becomes exhausted, and added ammonia having then no pyrogallic acid to assist its work, only produces surface-fog instead of continuing to develop the negative.

It should also be remembered that the amount of pyrogallic acid used at the commencement of the development has a very great effect upon the density of the resulting negative, and it is a most interesting experiment to make, to cut a plate in half after exposure, developing one half with one minim to the drachm of pyrogallic acid, and the other half with six minims to the drachm of the same solution; this will show clearly the very great power we have of

obtaining negatives of different character with alkaline development; and I may here take the opportunity of pointing out that, to properly develop a transparency, a small amount of pyrogallic acid only is essential, as otherwise the shadows block and become too dense and hard. I should have liked to have gone much more in detail into this subject had time permitted, but I will conclude by giving a formula for strong and very portable solutions for those who are travelling about with dry plates:—

No. 1.—Pure strong carbonate of ammonia	80 grains
Water	... .. 1 ounce
No. 2.—Bromide of potassium	... .. 120 grains
Water	... .. 1 ounce
No. 3.—Pyrogallic acid	... .. 96 grains
Alcohol	... .. 1 ounce

To each drachm of No. 1 add one minim of No. 2, and from one to six minims of No. 3, according to the density of the negative required, remembering that it is always well not to have too much pyrogallic acid in the developer to begin with, in case strongly lighted objects should thus come too dense at first; whereas, if we begin with from one to two drops of pyrogallic acid to each drachm, any amount of density can gradually be obtained by continued additions of two or three drops at a time of the pyrogallic acid solution.

If it is desired to replace the carbonate of ammonia by liquid ammonia, make up the developer with distilled water instead of the carbonate of ammonia solution, and to each drachm thereof add, as before, one drop of No. 2 and the necessary amount of No. 3, and pour two or three times on and off the plate; then add to the developing solution strong liquid ammonia (specific gravity 880) in the proportion of two minims to each three minims that has been used of the bromide solution. The two formulæ will then stand thus for a stereo-sized plate:—

##### Carbonate of Ammonia Development.

80-grain solution of carbonate	... .. 3 drachms
120-grain solution of bromide of potassium	3 minims
96-grain solution of pyrogallic acid (say)	6 ..

##### Liquid Ammonia Development.

Distilled water	... .. 3 drachms
120-grain solution of bromide of potassium	3 minims
96-grain solution of pyrogallic acid (say)	6 ..

Pour off and on, and then add strong liquid ammonia, 880.2 minims. If more density is required, add more pyrogallic acid; if more detail wants to be brought out, add more ammonia, and some pyrogallic acid therewith.

I feel sure that no one who gives this method a fair trial will return to the use of a weak alkaline developer; for while, by the strong developer, the sensitiveness of the plate is immensely increased, the chances of a plate fogging are infinitely less than with the old-fashioned weak developer.

It should be noted that this system of development is suited to gum gallic, tannin, beer, and other bath plates, as well as emulsion plates.

I show two negatives of different densities.

#### GELATINE AS A VEHICLE FOR SILVER SALTS IN THE PRODUCTION OF NEGATIVES.

BY JOSHUA KING, M.A.\*

THOUGH the use of gelatine as a vehicle for the salts of silver sensitive to the action of light was suggested as early as 1869 by Dr. Maddox, and the problem of its successful application was solved last year very completely by Mr. Burgess, of Peckham, no formula or method of working has been hitherto submitted to the criticism which a body constituted, like this society, both of

\* Read before the Photographic Society of London.

\* Read before the London Photographic Society.

scientific experts and skilled manipulators, can bring to bear on such subjects. Nothing as yet has been done to elicit an authoritative opinion as to the value of the innovation; and as those who have placed their preparations of gelatine in the market have naturally kept their secrets to themselves, the only point which societies have had to discuss hitherto has been the merits or shortcomings of the negatives produced by their aid. Under these circumstances it has been suggested to me that as I have published the results of my experiments, which have led me to a process moderately simple and certain, I should invite the society to give an opinion on my method, in the hope that discussion may settle the question as to the value of gelatine when used as a substitute for collodion.

I come before you, therefore, not as a successful inventor, but as a modest enquirer; and in this character I hope that, though the cause I plead for may fail to secure your verdict, the failure may not be credited to the presumption of the advocate.

The only combination I have at present tried is that of gelatine and bromide of silver. I had practised Mr. Carey Lea's chloro-bromide process in India, and have become a convert to the emulsion school of dry-plate workers. My first trials with Burgess's gelatine plates were successful, and I thought I recognised in the negatives a delicacy and softness not often seen in dry-plate work; but with the second batch of plates I was not so fortunate, and this failure induced me to attempt to prepare gelatine plates myself. Following in the tracks of Dr. Maddox and his disciples, I made trial of various proportions of gelatine in solution with ammonium or potassium bromide, and sensitized by equivalent weights of silver nitrate. But though I succeeded in getting sensitive films and a bright image with a very moderate exposure, all my negatives at this stage were useless, because the nitrates with which the emulsions were loaded crystallized out on the surface of the plates, and covered them with a web of seams and scars. I then tried a plan recommended by Mr. Sutton as likely to succeed; and having obtained my bromide of silver, by precipitation from aqueous solutions, I added it to my gelatine solution; but the result—possibly owing to my want of skill—was worse than the original failures: the mixture refused to emulsify properly, and the images were feeble and fogged.

While thus perplexed, I happened to remember that the process of dialysis would separate crystalloid from colloid bodies, and having Griffin's "Chemical Handicraft" by me, I consulted it; I had had no previous experience with the process myself, so I was startled to find that twenty-four hours were spoken of as the time necessary for an operation, and as gelatine was a substance with the peculiar properties of which I was little acquainted, I mentioned the matter to Prof. Living, and asked his advice. He told me at once that dialysis would serve me, and that four or five hours' diffusion would do all that I wanted. He also kindly explained to me the uses of the apparatus, lending me one of his own to begin experiments with. After one or two trials with a makeshift dialyser, which I contrived out of a wide-mouthed bottle, and with which I cleared the remains of some old emulsions which I had by me, to my entire satisfaction, I dialysed an emulsion made as follows:—Forty grains of gelatine were soaked in fourteen drachms of distilled water for four or five hours. Solution was then effected by heat, and twenty-one grains of potassium bromide were added to the dissolved gelatine. Thirty grains of silver nitrate dissolved in one drachm of distilled water, to which, after solution, three drachms of rectified alcohol were added, were placed in a glass vessel, and the warm bronzed gelatine was poured in a slender stream into the silver solution, the mixture being stirred actively with a glass rod. The resulting emulsion, which had a slight opalescent tinge, was poured into the dialyser and submitted for about four hours to the action of com-

mon spring water at a temperature of about 100° F. to begin with, the apparatus being placed near a fire, so that the gelatine might not become chilled during the operation.

Plates coated with this emulsion, which was milk-white, dried during the night, and in the morning showed no signs of crystallization, except about the thickened edges. Tried in the camera they were about as sensitive as the Burgess plates, gave fair printing density under alkaline development alone, with good details and freedom from fog.

I do not think that the proportions I have given are the best possible, but I have not been able to carry on any experiments with a view to modify them; and as the formula has given me good plates without a failure, as far as sensitiveness and brightness are concerned, I do not complain of it. I ought, however, to confess that I have sometimes been troubled by the film blistering and leaving the glass at the edges during development, and that I am somewhat at a loss to account for this mishap.

There can be no doubt that the tendency to blister will be found if the plates are developed before they are thoroughly dry, and the remedy is then obvious; but I have also remarked it in plates where the films were apparently in excellent order, and it has puzzled me greatly.

In such cases the blistering commences in, and is almost entirely confined to, portions of the plate either protected by the rabbet of the slide from the action of light, or exposed to its feeblest radiations; and I have found it a good plan to mask the negative after exposure, leaving a margin uncovered, and in that condition to expose it to strong light, which is tolerably effectual. This, however, is but a makeshift expedient, and I only mention it because it involves a question which is worth investigating with reference to the properties of gelatine, viz., whether the light acting on gelatine in combination with the haloid salts of silver does not in some way affect the tendency of that substance to absorb water.

I was at one time inclined to think that if the gelatine mixture becomes too much concentrated by evaporation, this disposition to blister is developed, and that a reduction in the initial strength of the solution would be a safe modification; but the few experiments I have had time to make have not confirmed this view. At all events, the difficulty appears to be purely mechanical; and though it has embarrassed me, I have no fear that the remedy will not be forthcoming as soon as the cause of the disease is ascertained.

It seems unnecessary for me to trouble you with any elaborately detailed account of the method I use for coating and drying the plates. There are manipulatory difficulties to be met in coating which will suggest themselves to every operator; but they are more formidable in theory than in practice, requiring a little knack and neatness to overcome them, but yielding readily to patience and perseverance. I use a glass rod to enable me to get an even film, and place the coated plates on a level shelf till the films are sufficiently set to allow the glasses to be reared up without disturbing the evenness of the coating, which takes some hours. I tried drying then in a box fitted with horizontal grooves about half an inch apart, into which the plates were slid ten minutes or so after coating, and in the bottom of which I placed a saucer of chloride of calcium; but I found that the evenness of the film was destroyed by the imperfect level of the plates in the box, and drying was a very slow process indeed; still I think that something of the sort might be devised, and the matter might usefully exercise the ingenuity of the numerous practical men to whom we owe so much of the compactness and efficiency of our present apparatus. The box must be of rather large dimensions; but it might be utilized as a packing-case when not employed upon its proper functions.

## GELATINE AS A SUBSTITUTE FOR COLLODION.

The idea of using gelatine as a vehicle for the sensitive salts of silver is an old one. Considerably upwards of a dozen years ago, M. Poitevin published details of several interesting experiments in this direction. Upwards of nine years ago we formed an emulsion of chloride of silver in a solution of gelatine; but finding a tendency in the film to dissolve in the fixing bath, we did not follow out the process. Subsequently a successful gelatino-chloride of silver process was published by Mr. Palmer, and a similar process was patented by Mr. W. H. Smith. The use of a similar emulsion of bromide of silver for producing sensitive dry plates which has for some time past excited attention was very prominently brought before the Photographic Society at its last meeting, when two papers on the subject were read.

Mr. King's paper is an interesting record of the effort of an enthusiastic amateur in overcoming the difficulties inevitable in working in a new path with few landmarks to guide him. The chief difficulty he experienced consisted in getting rid of the by-product resulting from the formation of an emulsion by a process of double decomposition. This mode of forming the emulsion is obviously the most easy and perfect, but unless the soluble nitrate of potash—formed when bromide of silver is obtained by adding nitrate of silver to bromide of potassium—and any free nitrate of silver or bromide of potassium which may be present, are removed from the emulsion, the dry plate is covered with crystals, which necessarily mar the negative. The removal of all crystallizable salts, it will be seen, must be removed from the emulsion, and at first sight this presents a serious difficulty. The plan of preparing the bromide of silver first, and then mixing it with the gelatine, was found impracticable. Mr. King then tried the process—very obvious and natural for the purpose—of dialysis. Our readers know that this process presents a ready and certain method of separating colloid, or gelatinous, and crystalline bodies, and hence the soluble crystalline salts left in the gelatine after bromide of silver had been formed by double decomposition were completely removed. But this process is slow and tedious, and, as Mr. Kennett observed at the meeting, for all practical purposes useless.

To meet the difficulty in a simple and perfectly practical manner, Mr. Kennett comes forward with his process, and although it is patented, its results are offered to photographers on terms which must preclude the thought of objection, to any reasonable man. Mr. Kennett, like Mr. King, forms his bromide of silver in the gelatine by

adding solutions of nitrate of silver and bromide of potassium in as nearly as possible their combining proportions. He gets rid of excess of either, and of the nitrate of potash formed, by a very simple process. He forms it into layers about a quarter of an inch thick, and allow it to set, then cuts it into strips, to expose as much surface as possible, and washes it in cold water, which, without dissolving the gelatine, removes soluble salts. It may then be used at once, or it may be dried, and preserved for use at any time, on redissolving by the aid of hot water. It will be observed that the final aim of the process is to obtain a film of pure bromide of silver, without excess of either bromine or silver, in a film composed of an organic substance capable of forming organic combinations with silver salts. Such a film is found in practice to be as sensitive as a film produced by the ordinary wet collodion process; and in the dry form, kept preserved from light, moisture, or other disturbing causes, the sensitive pellicle may, it would seem, be kept indefinitely. In this state of dried shreds it is supplied by Mr. Kennett to photographers, and, from the majority of the accounts we have heard of it, is found to work well and satisfactorily, yielding negatives of great delicacy.

But for those photographers who prefer to prepare their own materials Mr. Kennett's method furnishes a simple suggestion as to the best method of getting rid of crystallizable salts. After preparing an emulsion by dissolving the soluble bromide and nitrate of silver, in as nearly as possible their combining proportions, in a solution of gelatine, and preparing plates with the emulsion so obtained, it will only be necessary, after allowing the film to set well, to place the plates for a short time in water, or even to rinse well under a tap, to get rid of the soluble salts—just as Mr. Kennett gets rid of it from his pellicle by washing after it is set. A comparatively slight washing, it is probable, will remove sufficient of the salts to prevent crystallization on the surface. In our own early experiments with an emulsion of chloride of silver in gelatine, we rarely found any difficulty with crystallization, but frequently found the film dissolve in the hyposulphite fixing bath. In occasional instances this has been found to occur, we believe, with gelatino-bromide films. In preventing this, much will depend on the quality of the gelatine, and it is probable that the sample prepared by Nelson expressly for photographic purposes will be found to meet the difficulty. In the method patented by Mr. Smith, he was in the habit of allowing the gelatine used for his emulsion to decompose until it had lost the ready power of setting, and drying the coated plates by the aid of considerable heat in an oven, after which he never found the film to dissolve in fixing or washing.

Mr. Kennett's method presents facilities for working of so simple and desirable a kind that few dry-plate workers, we fancy, will fail, at least, to try his process. That there remain some difficulties to meet in a new process is a matter of course. In one instance an eminent foreign photographer writes to us that he has failed to secure an image of any kind by the process. An explanation of such failure will, doubtless, be found, and we hope shortly to investigate the special case and the special material used. Other difficulties have also been found, and have been overcome. We shall be glad to aid in establishing the process in its real place in photographic operations by giving publicity to the results of experiments of any of our readers.

## ENERGETIC DEVELOPERS.

THE discovery and application of more energetic developing agents than those now in use presents to the photographic experimentalist one of the most promising and useful fields for research. Gallie acid, pyrogallie acid, and the salts of iron, and occasionally combinations of two of them, were for many years the sole agents used in developing the latent image. Something like ten or a dozen years ago,

some fine instantaneous stereoscopic negatives on dry plates were produced, as we were informed in confidence, by means of a developer consisting of a saturated solution of gallic acid which contained, in addition, twelve grains of pyrogallic acid to each ounce. The first great advance in dry plate development was made, however, when Mr. Leaby discovered the principle of alkaline development by using ammonia. Since then the method has been worked out, systematized, and improved by various dry plate workers, but by none more effectually than Col. Stuart Wortley, whose discovery of the value of solutions of ammonia of a strength before undreamed of was one of the most marked steps of progress in this direction. A note presented by the same gentleman at the last meeting of the Photographic Society is suggestive of further improvement in the increased power it places in the hands of the photographer. By the use of the concentrated solution of ammonia, the power of obtaining perfect detail with considerably decreased exposure was secured. He now points out—and he verified his statement by exhibiting admirably illustrative negatives—that, by properly varying the proportion of pyrogallic acid to the increased ammonia, enormous control over the intensity of the negative is obtained. To secure brevity of exposure and fulness of detail, full doses of ammonia must be employed; and to secure vigour and intensity, the proportion of pyrogallic acid must be used. One of the greatest points of importance in connection with these advantages in development is found in the fact that they are applicable to all kinds of dry plates suitable for alkaline development, and are not confined to emulsion plates only.

#### FURTHER EXPERIENCES WITH THE PLUMBAGO PROCESS.

BY WALTER WOODBURY.

SINCE writing my last article, I have made some further researches in this useful method. The greatest difficulty I experienced was, the getting the glass into such a state that the film should take evenly all over it. No matter how chemically clean we get the glass, there still seems a tendency of the solution to leave it in patches. To obviate this, I now proceed in another manner, which, besides getting over this difficulty entirely, possesses other advantages.

I take the glass (in this case extra cleanliness not being so much an object) and coat it with a thin, porous, plain collodion. When thoroughly set, I wash it under a tap until all greasiness disappears. I now let it drain on blotting-paper for a short time, and having taken a small quantity of the sensitive solution, freshly filtered, I pour it over the plate several times, each time from an opposite corner. After draining for a short time, I dry it over a Bunsen, expose, and develop it in the usual manner. When sufficiently developed, I coat it again with collodion, but this time with a much thicker sample, and, having levelled it, leave it to dry. When this has been accomplished, I place it in a bath of water acidulated with hydrochloric acid, when, after a short space of time, the film detaches itself from the glass, and should be placed between blotting-paper till dry. The coating of the sensitive gum solution prevents the thick collodion from dissolving the thin, the image being protected on both sides. I think this a far better method of getting a reversed negative than running the risk of removing from its support a valuable negative; and as plate glass must be used in this method of reproducing negatives, the extra time and trouble of removing them is less than the value of the plate glass, besides the advantage of being able to print from either side.

The same principle by which the plumbago negatives are made has been utilized by my friend Mr. G. Whitfield for strengthening ordinary negatives, and, from my own experience, I think this will prove a very valuable appli-

cation, as the intensifying may, so to speak, be localized, and effects got that could not be obtained by the ordinary methods of re-developing. Having taken a negative, and developed with iron, allow the superfluous moisture to drain away, and proceed exactly as I have described in the earlier part of this article—that is, coat with the sensitive solution, dry, and expose to light. The black-lead may then be applied until the desired effect is produced—the most work being laid on a weak foreground, for instance, and the least on a delicate sky, thus avoiding that want of harmony so often found in a negative re-developed in the ordinary way. It must be borne in mind that the black-lead process will not bring out more detail, which may be often accomplished by silver re-developing, although I have noticed that details in the blacks that could hardly be observed were made to show plainly.

#### IODIDE OF SILVER IN THE DIPPING BATH.

BY DR. H. VOGEL.\*

IN continuation of my paper "on sensitiveness,†" I propose now to cite a few examples of how one and the same formula will yield perfectly different results in the hands of different operators, and how the slightest of modifications are capable of bringing about the widest discrepancies in one's work.

For the last seven years I have employed a formula for the preparation of collodion for my own private use. From different sides I have been asked for information on the matter, and I have given particulars to all who desired them. Many practical photographers in Berlin worked with it successfully, and at last I published the whole proceedings. I will give the formula here.

Eighteen grammes of iodide of cadmium were dissolved in 270 cubic centimetres of alcohol, and seventeen grammes of bromide of cadmium likewise in 270 cub. cents. of the same. Both solutions were filtered, and five parts of the iodized salt solution were mixed with one part of the bromine salt solution (the quantities taken by measure), and eighteen parts of normal collodion made with two per cent. of pyroxyline were added. The collodion was then ready for use.

I am far from putting this collodion forward as a universal instantaneous collodion. I only wish it to be understood that it has given me good results, whether as regards the clearness and detailed character of results, or the sensitiveness of the film. It has, too, been kept for years in the studios here.

Lately a gentleman in the provinces whom I knew to be a most skilful photographer informed me that he had also essayed my collodion, and could make nothing of it. It yielded, so he said, too thin a film, was probably too weakly iodized, gave no vigour to the picture, &c., &c. In proof of these complaints some plates were forwarded taken with my collodion, together with others produced with a commercial sample of instantaneous collodion, for the purpose of instituting a comparison. The sight of these was enough to make anyone blush. The images prepared with my collodion were grey and flat; and those with the other brilliant and vigorous; and the assurance was appended that both collodions were worked in the same silver bath, with the same developer, and the same intensifier. It availed nothing sending my correspondent a collodion prepared with my own hands, which had given me brilliant results, for the defects still remained; until one day, travelling in the neighbourhood, I visited the gentleman in question, and prepared some plates in his presence.

At once the cause of the error proclaimed itself. The plates prepared with my collodion came perfectly pale and exhausted from the sensitizing solution, and it was clear that the dipping bath contained very little iodide of silver, and it was for this reason that it attacked the film. 1

\* Photographisches Notizen.

† See PHOTOGRAPHIC NEWS 29th May last.

asked here how he iodised his bath, and he told me by leaving a collodionised plate in the freshly made-up solution during the night. This method of iodising is one very frequently employed, but it is not a very trustworthy one, for no one knows how much iodide of silver goes over from the film into the bath. Such rule-of-thumb practices I do not like. I always want to know the constitution of my bath, and for this reason I iodise the silver solution in the following manner. I take—

Nitrate of silver ... ..	100 grammes
Water ... ..	1000 "
Iodide of cadmium solution	25 cub. cents.
Nitric acid ... ..	3 drops.

The iodide of cadmium solution is made up of one part of iodide and a hundred parts of water.

The nitrate of silver is in the first place dissolved, and the iodide of cadmium solution is then added while the liquid is being thoroughly stirred. A precipitate is at once formed on the addition of the iodide, but this soon disappears again. The bath thus obtained is about three-quarters saturated with iodide, and any attack upon a collodion plate is no longer to be feared.

I at once prepared a bath of this kind, and forthwith proceeded to sensitize a collodion plate of my own with this solution. It turned out faultless, thus affording proof how a very small circumstance, as the silver bath lacking a slight quantity of silver iodide, is sufficient to make the obtaining of successful results impossible. When commercial collodions do yield good negatives in such baths, it is because they contain, as a rule, a large proportion of sensitising salts. For this reason they sustain an attack from the dipping bath with greater impunity, for there still remains always sufficient iodide of silver to give an intense image.

In time, of course, matters alter. Gradually the bath, after a series of plates have been dipped in it, becomes more and more saturated with iodide of silver, and at last it contains so much that the plates are not attacked, but, on the contrary, become denser, the iodide of silver precipitating upon the film.

The condition of the plates is then totally different to what they were when the bath was fresh, and eat into the collodion film. Such great contrasts are not met with when a moderately salted collodion, and a bath prepared accordingly to my formula, are employed. Both extremes are then avoided, for the super-saturation of the bath with iodide of silver comes on more slowly with a collodion containing less sensitizing salt.

Many misconceptions arise, too, in respect to the quantity of iodide of silver contained in baths which have been renovated and doctored. It is customary to precipitate a portion of the iodide of silver by dilution with water. The more water is added, the more iodide of silver is thrown down. Not unfrequently, the amount that remains behind is so insignificant that the bath again attacks the plates. A bath which is correctly iodised will allow of an addition of two or two-and-a-half cubic centimetres of water to every ten centimetres of bath before it becomes permanently turbid. In this way the degree to which the silver bath is iodised may easily be ascertained. Ten cubic centimetres of the silver bath are put into a glass vessel (a graduated measure is best), and distilled water is added drop by drop, agitating the liquid meanwhile. A point is soon reached when the precipitate formed does not again disappear on shaking, and then the addition of water is discontinued. Too strongly iodised baths will not bear the addition of so much as two centimetres, while one containing the iodide in small proportion will allow of the addition of two-and-a-half centimetres. The latter should be tested by the careful addition of a little iodide of potassium solution.

Finally, I should mention the important circumstance that iodide of silver is capable of being dissolved in much larger quantities in a cold bath than in a warm one; and

for this reason it is that at a high temperature the iodide is more apt to be precipitated from a dipping bath than in a low one—that is to say, more readily in summer than in winter. When the crystallizing out of the iodide takes place, then, as every photographer knows, there appear endless little pinholes in the collodion film.

I have now for more than ten years past pointed out this decrease of solubility of iodide of silver in a warm solution, but one still sees the fact ignored in so many manuals and handbooks of photography, that it does good to come back now and then to the oft-repeated maxim.

#### NOTE UPON THE FOCUSING OF SPECTRUM LINES IN SPECTROSCOPIC OR ASTRONOMICAL OBSERVATIONS.

BY DR. D. VAN MONCKHOVEN.\*

If an examination is made of plate I., spectrum B, line G, with a microscope magnifying twenty diameters, and especially of the parts marked 2,625 and 2,800 of Kirchoff, there will be seen a multitude of fine lines. To observe these lines in a spectroscope fitted with four prisms of flint glass, a comparatively powerful magnifier is necessary. From this it may be guessed how difficult is the focussing of such an image. If an error is made to the extent only of a thousandth part of the focal length of the lens, a great loss of sharpness ensues.

Now if a ground glass is used, produced with the finest emery powder, none of these fine lines are at all visible. The structure of the ground glass itself, viewed under a powerful magnifier, is very coarse; and if a line is drawn upon it with a hard blacklead pencil sharpened to a fine point, the line is thickened, on account of the grain on the glass.

The focussing of the fine lines of the spectrum, or of microscopic objects reflected upon a screen, or of celestial bodies, is therefore impossible with the aid of a ground-glass screen. It has been proposed to replace the same with a collodion plate exposed, developed, and fixed. In this way a transparent plate is secured, upon which is deposited a very fine precipitate of silver. By employing a magnifier of Ramsden's construction, it is possible to focus at one time the particles of reduced silver upon the film of collodion and the image. But, after all, this is very difficult in practice; for the silver deposit still presents too coarse a grain, and the finer objects are not seen at all.

Sometimes Ramsden's eyepiece is employed, adjusted in such a manner (upon a transparent, polished glass plate) that one side of the plate is in focus, and then the ground glass is replaced by a sheet of ordinary transparent glass. This method, however, simple enough in theory, gives rise to serious errors in practice.

The plan I adopt is the following:—To focus delicate objects, I move the ground glass to and fro in its proper plane; and to accomplish this the ground glass is placed in a frame adapted to the purpose. The grain disappears by the effect of the retention of the image upon the retina for a certain time, in the same way as the teeth of a cog-wheel disappear when the latter revolves rapidly.

The method is a very simple one, and is well adapted for projecting the lines of the ordinary spectrum. But when it is a question of very fine lines, such as the delicate one between the lines D and U' of the spectrum, then I make a revolving disk of glass covered with a film of very thin collodion, which is sensitized, exposed, and fixed. It is necessary that the glass be very flat. Then, on applying the microscope, it is possible to focus the finest lines of the spectrum, as also the most delicate astronomical objects, such as the companion of *Polaris*, &c.

Many who have experienced difficulties in focussing for very minute objects will find, I think, the method I have here indicated to be a very useful one.

\* Read before the Photographic Society of London.

## PHOTOGRAPHY FROM A SANITARY POINT OF VIEW.

BY DR. H. NAPIAS.\*

*Preliminary Remarks.*—The exercise of every trade and profession brings with it a series of ailments or peculiar maladies which are oftentimes dangerous, and sometimes mortal.

These *maladies of toil*, very numerous and very various, are due either to the nature of the work performed, to the character of the factory or office in which that work is undertaken, to the atmosphere that is breathed, and to the materials with which one has to labour; and if to these different causes we add those which are connected with one's mode of living, we shall have indicated the origin of nine-tenths of the maladies or infirmities that can afflict the human race.

The medical questions inherent to the sufficiency or insufficiency of one's means, as also to one's intelligence or ignorance, offer a wide and interesting field of study, and are, at the same time, of great importance from an economical and philosophic point of view, for it may be said that they exert the most direct influence and energy upon our health and upon the morality of our artizan classes. But these are questions relating to general hygiene, intimately connected with political and social economy, and which we shall not here discuss, as they lead us very much from the path we have proposed to follow.

Maladies, whatever may be their causes, have been provided by medical science with prescriptions and remedies, preventive, palliative, and curative. The aim of medicine, in fact, ought to be, according to the nature of the circumstances, to prevent the malady if possible, to palliate its gravity, or to effect a radical cure when it has neither been foreseen nor prevented.

We call that portion of the medical art hygiene which relates more particularly to preventing the development of maladies by means of a certain number of precautions indicated by experience and common sense, and by the teachings of science. Hygiene is, in a word, the art of preserving one's health.

Professional hygiene is the special hygiene of each profession; that is, the sum of means capable of destroying or lessening the bad influences inherent to such or such a form of labour.

From what we have said, the importance of hygiene may be easily understood, and it would be a good thing, indeed, if everybody understood its elements. It seems to us that such knowledge should form part of the preliminary instruction in schools, the study of general hygiene being afterwards supplemented, when a profession or trade has been chosen, by an acquirement of the elements of professional hygiene.

The profession of photography, like all others, has its inconveniences and dangers from a sanitary point of view. No matter whether those who occupy themselves with the art are, in general, better instructed than those who devote themselves to other labours, or whether the salary is ordinarily enough, and sufficiently remunerative, to guard them from the lower morbid influences, such as result from physical and moral misery—two things signifying indigence and ignorance—they are still exposed to a certain number of baneful influences, due to the circumstance that they have for the greater part of the day to live in an atmosphere charged with ethereal vapours, to manipulate noxious chemical substances, and to submit to other matters of a prejudicial character, which we shall allude to hereafter.

We propose, in this little work, to pass in review these different influences, to demonstrate their serious nature, and to indicate the best means to lessen their grave effects upon the system.

*Of the atmosphere of photographic studios.*—The presence in the laboratories and photographic work-rooms of a large number of chemical products, some of which are very volatile, have the effect of vitiating the atmosphere and charging it with foreign vapours. Among these substances alcohol and ether stand in the first rank, and particularly merit our attention. Alcohol and ether, so constantly employed in photography, and so volatile in their nature, charge the air with their vapours; and the higher the temperature is, the greater is the quantity of vapour disengaged, a reason why the evil is aggravated in summer, and by the glazing of the studios.

The first effect of this mixture of alcohol and ether upon the air is to communicate to it a characteristic and penetrating odour, which exerts a different effect upon different people, but to which they are not long in completely habituating themselves. At the same time, some photographers, after practising their calling for some time, feel, they tell me, when they have worked long in the laboratory, a giddiness, and sometimes even a disposition to vomit, and, more often still, a bad headache. With others there is nothing of this kind, but the appetite diminishes, and sleep becomes bad and irregular, or sometimes is wanting altogether. With others, again, the continual inhalation of the ether vapour occasions cerebral excitement, which is not altogether unconnected with inebriation.

These few words suffice to show in what different ways an atmosphere charged with ether and alcohol vapours may influence the health of photographers. Sometimes this influence is quite imperceptible upon the patient himself, or, at any rate, he does not attribute to it the cause of the maladies which, in certain cases, may result from it, such as bronchitis, inflammation of the lungs, and congestion of the brain.

Whatever accidents may arise from living continually in a certain atmosphere, we may state that in order to avoid—or, in any case, not to augment—the bad effects, the first hygienic condition to fulfil is to partake but very moderately of alcoholic liquors. If the abuse of alcohol upon man (whatever may be his profession) exerts the most baneful of influences; if it is the origin of so many diseases, and also, we may say, of so many vices and crimes; if it is the main reason for most of the follies that are committed, since more than a third of the insane owe to it their loss of reason; if, because of all this, it behoves every one to guard himself above all against the terrible habit of drunkenness, it is of much graver consequence to do so in professions like that of the photographer, who is exposed daily to the inhalation of ethereal vapours, against which he must fight and defend himself.

Alcohol absorbed into the system is supplemented in its action by the ether breathed through the nostrils, and thus the injurious effects of the former are exaggerated or are germinated in those who would otherwise have escaped them.

A sojourn at the café or tavern on quitting the studio may be replaced with advantage by a long walk in the open air; and in warm weather the best drink that we can recommend photographers to refresh themselves with is lemonade, seltzer water, or other acidulated liquors, which tend to annihilate the effects of the ether fumes. A good thing in the morning before proceeding to work, or at night on coming home, is a glass of claret and quinquina, made simply with *vin ordinaire* and yellow quinquina, which serves, on account of the tannin and quinic it contains, to counterbalance the effects of the ether, and, at the same time, excites the appetite and favours digestion. By preparing it oneself the cost is not very great, certainly much less than the Vermont sold at cafés and cabarets, a slow poison which people take day by day under the name of absinthe. If acid drinks do not suffice to get rid of the headaches with which photographers are so often troubled, a few drops of ammonia or vinegar in a glass of sugar water will very often succeed.

Finally, we may add that this course of sanitary regime will be materially aided by suitable ventilation of the studios, and by continual renewal of the atmosphere that is breathed.

(To be continued.)

#### HAVING A PHOTOGRAPH TAKEN.

HAVING a photograph taken is one of the great events of a man's life. The chief desire is to look the very best, and on the success of the picture hinges, in many cases, the most important epoch in life. To work up a proper appearance time enough is used, which, if devoted to catching fleas for their phosphorus, would cancel the entire national debt, and establish a daily paper. When you have completed your toilet, you go to the gallery and force yourself into a nonchalance of expression that is too absurd for anything. Then you take the chair, spread your legs gracefully, appropriate a calm and indifferent look, and commence to perspire. An attenuated man, with a pale face, long hair, and a soiled nose, now comes out of a cavern and adjusts the camera. Then he goes back of you, and tells you to sit back as far as you can in the chair, and that it has been a remarkably backward spring. After getting you back till your spine interferes with the chair itself, he shoves your head into a pair of ice-tongs, and dashes at the camera again. Here, with a piece of discoloured velvet over his head, he bombards you in this manner:—"Your chin out a little, please." The chin is protruded. "That's nicely; now a little more." The chin advances again, and the pomade commences to melt and start for freedom. Then he comes back to you and slaps one of your hands on your leg in such a position as to give you the appearance of trying to lift it overhead. The other is turned under itself, and has become so sweaty that you begin to fear it will stick there permanently. A new stream of pomade finds its way out and starts downward. Then he shakes your head in the tongs till it settles right, and says it looks like rain, and puts your chin out again, and punches out your chest, and says he doesn't know what the poor are to do next winter unless there is a radical change in affairs; and then takes the top of your head in one hand, and your chin in the other, and gives your neck a wrench that would earn any other man a prominent position in a new hospital. Then he runs his hand through your hair and scratches your scalp, and steps back to the camera and the injured velvet for another look. By this time new sweat and pomade have started out. The whites of your eyes show unpleasantly, and your whole body feels as if it had been visited by an enormous cramp, and another and much bigger one was momentarily expected. Then he points at something for you to look at, and tells you to look cheerful and composed, and snatches away the velvet and pulls out his watch. When he gets tired, and you feel as if there was but very little left in this world to live for, he restores the velvet, says it is an unfavourable day for a picture, but he hopes for the best, and immediately disappears in his den. Then you get up and stretch yourself, slap on your hat, and immediately sneak home, feeling mean, humbled altogether, and too wretched for description. The first friend who sees the picture says he can see enough resemblance to make certain that it is you, but you have tried to look too formal to be natural and graceful.—*Danbury News.*

#### Correspondence.

##### THE COLLODIO-CHLORIDE PROCESS.

SIR,—There is prevalent at this season of the year, in gardens, fields, and by hedgesides, an offensive pest known to entomologists as the *Tettigonia Spumaria*, and to the unscientific public as the cuckoo-spit. It generally attaches itself to the leaves and branches of the most choice and fragrant plants, battenning upon their vital

juices, but enveloping itself in a mass of frothy spume, which hides the mischievous insect until the slimy ooze is removed in order to crush the offensive creature. I was reminded of this insect by a letter in your *Liverpool contemporary*, on the collodio-chloride process, chiefly consisting of frothy invective, intendo, and reiteration of oft-refuted misstatement. As regards the slanders the writer voids upon yourself, I shall not so far presume as to suppose that they need refutation. But there are two points in relation to my own letter in your pages upon which I shall ask permission to say a word. He does me the honour to identify my pen with yours, or that of one of your "touters." I think it is Tennyson who says that slanderers generally impute to others the vices to which they are themselves the most prone; and we might thus readily understand, therefore, the origin of the letter in question, even if the well-known vulgarity of style had not identified the writer beneath a pretended real signature. But he fails, with all his mendacity, to answer the challenge in my letter, in which I in effect call upon any one to produce evidence that he ever saw, or heard of the existence of, a collodio-chloride print until you published the process in your pages in 1864. Until this is done railing can serve no purpose but to degrade the railer.—Yours truly,  
FAIRPLAY.

#### A FICTITIOUS NAME.

SIR,—Without wishing to enter into a quarrel which, on one side at least, is too contemptible for notice, will you allow me, in the interests of a noble profession, the name of which is unscrupulously dragged into the dirt, to make a statement and protest. In a photographic journal published last week I find a vulgarly abusive letter signed "Henry Edward Thompson, M.D." Regret that a medical man should descend so low was my first feeling; doubt of the genuineness of the signature the second, which was strengthened by finding that this ostentatiously full signature was not accompanied by an address. A very easy reference showed me that no such person exists. To a very ignorant person the possibility of giving weight to a fictitious name by the addition of "M.D." might appear a very safe device. As it happens, there is no trick more easy to detect. The Government has made it imperative that every "M.D.," and, indeed, every qualified practitioner, should be duly registered, and there is no "Henry Edward Thompson" whatever in the "Medical Register," either in England, Ireland, or Scotland, nor amongst the medical officers of the army and navy. As to the skit on yourself, I should suppose you would consider it beneath notice; but I protest against the indignity to the medical profession involved in the use of the titular "M.D." to give fictitious weight to an attack which would have been vulgar and scurrilous if true, and which, being untrue, I will refrain from characterizing.—Your obedient servant,

G. V.

[We have received another letter calling our attention to the fact that there is no such name as that attached to the letter in question in the "Medical Register." Our correspondent is right in supposing that we should regard the slanderous drivel as beneath contempt, nor shall we comment on the decency of the attempt to give it a factitious appearance of weight.—Ed.]

#### ABUSIVE JOURNALISM.

DEAR SIR,—The status of photography in the social world is becoming worse and worse, and our highest and cleverest professors bewail their condition. This is bad enough; but, added to this state of things, we seem to be drifting into a chronic condition of antagonism amongst ourselves, which results in giving license to the worst passions of the human mind. Why this should be so appears a most difficult problem to solve. Can it be that the practice of photography so re-acts upon the whole system that all the worst moral qualities of the heart become developed to an unusual extent, and a tendency to attacks of irritability the result, which seem to dry up all the kind and courteous capabilities of our nature?

In the early days of photography such used not to be the case, so that it would seem to follow that after a few years devoted to the close practice of the art, these dangerous symptoms set in. If so, let our young aspirants to fame and position pause, and seriously think about what can be done to act as a check upon so grievous and melancholy a condition of matters, which now seems to pervade so many of our advanced members.

I am led to these thoughts not only by recent events, but more especially by the publication, in a contemporary, of various letters and observations, all showing such an unkind and, I might almost say, savage condition of mind, that one cannot but feel

pained and subdued, feeling that if such is to be the result when differences of opinion upon any subject arise, how little of that high moral principle of wishing to "do unto others as we would wish others to do unto us" is extant amongst photographers.

There is, however, just one ray of comfort which we have, and that is, that despite numberless provocations, and all that is calculated to rouse up angry feelings, the PHOTOGRAPHIC NEWS has shown a determination to refrain from the slightest exhibition of that painful and fatal resource of vulgar, ungenerous minds—"personal abuse." We photographers, if ever any social position is to be conceded us, must endeavour to conform to all those laws and customs which the refined and polished circles of society intuitively respect and follow.

Feeling personally very strongly the loss of status incurred by photographers, and believing that the many are suffering for the shortcomings of the few, I call upon all who value right conduct and the cultivation of the amenities of good society to show, in some way or another, that they do not indorse such ill-judged and extravagant language, which disgraces our literature, and is difficult to combat with, for it is like a chimney sweep in a crowd—the respectable stand on one side, fearing contact and contamination.—Yours, &c.,  
INDIGNANT.

NEW LAWS OF THE PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Please insert the following in Friday's NEWS, and oblige your truly,  
GEO. HOOPER.

SPECIAL NOTICE.

THE New Laws will be in the hands of members not later than Monday next, and a special general meeting for passing same will be held at 9, Conduit Street, Regent Street, W., at 8 p.m., on Tuesday, 30th June.  
GEO. HOOPER, Acting Secretary.

Winwood House, 68, Canonbury Park South, June 17.

ALBUMEN AND BEER PROCESS.

SIR,—In your columns of last week Mr. W. H. Davies fully establishes his claim to being the first to use albumen and beer as a preservative. I need scarcely say that I was unaware of the fact, as if I had been I should most certainly have mentioned it in my paper to the YEAR-BOOK. I must, however, draw attention to the fact that the mode of applying the preservative in the two cases is somewhat different, and, naturally, I am inclined to think that my own method is the better. I had tried Mr. Davies' plan originally, and abandoned it for that I now adopt. There are two essential differences between the two: I advocate rendering the albumen and beer very strongly alkaline, and also washing off any excess, and finally giving a varnish to the film of beer and pyrogallic; and Mr. Davies adds the gallic (or pyrogallic) acid to the albumen and beer, as also nitrate of silver, and allows the albumen to dry without washing afterwards. I lay great stress on rendering the film alkaline: it is an important means for securing rapidity. The exposure necessary for a wet plate is sufficient if so prepared. One advantage of washing off the albumen is, that Col. Wortley's strong alkaline developer can be used (minus the bromide), whereas with a thicker film of albumen it is mostly held that this developer is inadmissible.

There are certain other advantages in the final wash of beer and pyrogallic acid, which it is not necessary to detail. I think the difference between the two modes of working is about as large as between the Fothergill and Taupenot processes. Davies' process I am sure is excellent in every way, but by me has been found slow. I would ask him to give the modification a fair trial, using the strong alkaline development, with but short exposure. Perhaps he will find it worth continuing. Call either process by what name you will, they will both yield a high class of negatives.

Any one using alkaline albumen should try dissolving "dried albumen" in water rendered slightly alkaline by ammonia. Place twenty-five grains in a dish and boil them in one ounce of water. The liquid will be free from "strings," and perfectly limpid. This is about equivalent to the white of one egg. Dried albumen costs about eight shillings per pound, and can be obtained from a well-known manufacturing chemist. Blood albumen is nearly as good as ov-albumen.—Yours faithfully,  
W. DE W. ABNEY, Capt. R.E.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE last meeting of the present session of the South London Society was held in the rooms of the Society of Arts on the

evening of Thursday, June 11th, the Rev. F. F. STATHAM in the chair. The minutes of a previous meeting were read and confirmed.

Mr. HOWARD and Mr. FOXLEE stated their experiences with aurine for producing non-actinic glass, the former gentleman having used it in varnish, whilst the latter used collodion as the vehicle.

Mr. W. T. WILKINSON exhibited an ingenious plate-holder, similar to one he described in our pages, a modification consisting in placing the handle at the corner. After votes of thanks,

Mr. WHARTON SIMPSON, at the request of the president, gave a brief account of the theory and practice of the powder process as practised for the reproduction of negatives at one operation after which

Mr. WRATTEN, from the establishment of Mr. Solomon, gave a successful practical demonstration of the process, reproducing a portrait negative, and a negative of an engraving. He explained various points of detail as he proceeded. He used magnesium light, giving an exposure of about two and a quarter minutes, and using three feet of wire. This, he explained, would be about equivalent to five minutes of diffused daylight. He had produced a good enlargement on the sensitive surface with an exposure of fifteen minutes. The formula for the sensitive preparation which he employed differed somewhat from the other formulæ which he had seen published. It stood as follows:—

Dextrine	...	...	...	...	...	1 ounce
Grape sugar	...	...	...	...	...	"
Bichromate of ammonia	...	...	...	...	...	"
Water	...	...	...	...	...	1 pint

Some conversation on the relative advantages of bichromate of ammonia and bichromate of potash, in the course of which Mr. B. J. Edwards said that he found that the addition of a little ammonia to the bichromate of potash solution secured all the advantages of the ammonia salt at a cheap rate; and Mr. Simpson pointed out that this addition produced a double neutral salt, analogous in solubility and sensitiveness to the simple ammonia salt.

Mr. HOWARD showed some negatives which he had produced by this method, using very simple materials and appliances. He had followed generally the plan described by Mr. Woodbury in the journals, but, as he had no glucose at hand, he used ordinary white sugar. He took the lead of an ordinary lead pencil, and pounded it in a mortar for his graphite. Altogether he found the process easy and successful.

In answer to questions, Mr. WRATTEN said that with the aid of an assistant he could produce fifteen or twenty completed duplicates of negatives. He liked the graphite perfectly dry, and gave it a good roasting before use. He liked to work in a dry warm room.

Mr. B. J. EDWARDS had found it useful for strengthening negatives, or for obtaining a duplicate negative at the back of a thin negative giving the softened mezzotint effect, which had been described as produced by printing from two negatives. He exhibited two prints, one from an untreated negative, and the other from the same negative after a duplicate negative had been produced at the back, the latter having a pleasing softness, which was regarded as very effective.

Mr. TULLY showed an ingenious plate-vice for holding the glass during cleaning, simplicity in securing and releasing the plate being obtained by turning a handle working on a pivot fixed out of the centre.

Mr. W. T. WILKINSON said a similar holder had been described and figured in the YEAR BOOK OF PHOTOGRAPHY a few years ago (1869).

After some further conversation, and a vote of thanks to Mr. Wratten, the President gave his annual invitation to members to spend an evening at his house on the last Saturday in July. The proceedings then terminated.

Talk in the Studio.

PARSON'S SEMI-OPAQUE VARNISH.—We have examined and tried a bottle of Parson's semi-opaque varnish, and find it admirable. When applied either upon bare glass, the collodion film, or upon the surface of a varnished negative, it gives a matt translucent surface, like that of the finest ground glass, peculiarly well fitted for backing stereoscopic and other transparencies. It presents a very fine tooth to a lead pencil, permitting the most delicate retouching to be effected without coarseness or granularity. The surface is very even and very hard, and in every way satisfactory.

**ROBINSON'S SPOTTING-OUT COLOUR.**—We have received a bottle of Robinson's "spotting-out" colour, which every photographer will find a great boon, and having used it once, will scarcely be willing afterwards to forego its use. It possesses an unctuous quality which makes it easy and pleasant to work. It takes easily to the varnished surface, does not spread, permits very fine touches of either a semi-transparent or perfectly opaque character, and dries rapidly with precisely the same effect as when applied. Its exact constitution we do not know, but it possesses something of the quality of reduced silver, or the deposit which forms a negative, ground up with an essential oil. Whatever its constitution, it is a capital preparation for its purpose.

**TEAR-SPOTS ON SILVERED ALBUMEN PAPER.**—Mr. L. D. Judkins writes to the *Photographic Times* as follows:—"The first symptom of tear-spots on the drying of silvered albumen paper is the oily appearance on the silvered surface while drying, the free surplus silver running down the sheet in small rivulets, then breaking up into small globe-like bodies; and if left to dry, form what it is so often called tear-spots, which are a source of great annoyance to many photographers. If at any time your paper dries as above stated, pin the paper to a board at each corner with copper tacks, and whilst moist take a tuft of cotton and destroy the small bodies of silver as they form on the surface of the paper by brushing them away. But if the paper has become nearly surface dry, wet the tuft of cotton with the drip on the bottom of the sheet, and moisten the surface of the affected part again; the paper now assumes a smooth surface, and dries free from spots."

**BLEACHING IVORY, BONE, ETC., BY LIGHT.**—M. Clözé finds that exposure to the light of the sun for three or four days in oil of turpentine is a most efficacious process for bleaching bone, ivory, and some other articles. Bone and ivory thus treated become of a dazzling whiteness. The objects to be bleached must be suspended so as not to quite touch the bottom of the vessel containing them, as this is covered by a very thin acid layer produced during the operation. Other similar essential oils produce the same effect.

## Do Correspondents.

**THE COLLODIO-CHLORIDE PROCESS.**—We must apologise to several correspondents, who have sent communications for publication on this subject, for the non-insertion of their letters. As there is really no point requires elucidating, and, as Mr. Bovey remarked in our last, the process is freely given to the public, nothing can be gained by further discussion. We are perfectly satisfied with the recognition of the public of our authorship of the process, which has, indeed, never been disputed except by the petty jealousy of one without the rags of a reputation for originating anything. **AN OLD AMATEUR** writes to point out the fact that there is no such name as Henry Edward Thompson, M.D., in the "Medical Register," and asks, "What credence, then, can be given to any statement, on any subject, by a person who, writing anonymously, endeavours to obtain the authority of a personal identity by fabricating a name, and adding to it initials belonging to an educated profession?" Another correspondent, signing "R. A.," who heads his letter with the caption "Mad Dog," after some good remarks on the general subject of the Eatanswill style of journalistic writing, says:—"I purposely leave out of the present question all consideration of the collodio-chloride process: as none of the gentlemen who have written upon the subject claim the discovery for themselves, and those upon whom they would confer the honour have disclaimed, I think I may very well do so. It seems to me, from the style of several letters that have lately appeared, that a 'very pretty quarrel' has just commenced. The animus in more than one of these articles is manifest enough, but all 'pale their ineffectual fires' before one that appeared in last week's *Journal*, from the pen of a correspondent who adds 'M.D.' to his name. What is the meaning of this M.D.? Under ordinary circumstances, I should conclude the initial letters stood for Doctor of Medicine. Now I have the utmost admiration for the healing art.

"A leech well skilled our wounds to heal  
Is more than armies to the common weal,"

says (Pope's) Homer. Yet surely a professor of this noble art would never descend to maim and mangle a reputation in the style of this M.D.! It cannot be; and the snap, snarl, and bite of the whole course suggest, as much more appropriate, the heading of the present article. Certainly this correspondent does not do things by halves.

"Frontless and satire-proof he scours the streets,  
And runs an Indian muck at all he meets."

M.D. has made a discovery: he understands it is 'now' the fashion of the town—and country too, he might have said—to

quote Shakespeare. He is right for once, at any rate. It is a fact, although scarcely of the newest. The said fashion commenced in the reign of Queen Elizabeth, and has extended itself so far that at last it has even come to the knowledge of M.D. He has also, it would appear, made another discovery, in ascribing the letter of your correspondent 'Fairplay' to your editorial pen. Let he should make yet another, and hold you responsible for the present communication, I leave you at liberty to furnish my name to any one who may feel curious upon the subject, except to our discoverer himself. I am neither bashful nor timid, but, considering the season of the year, and the nature of his complaint, I decidedly object to a *tele-a-tele* with 'M.D.'—Yours truly, R. A." "T. P." and others will see that we cannot, with propriety, devote further space to the subject.

**A. B.**—Excess of intensity and lack of half-tone may proceed from many causes; but in the case you describe it probably arises from the collodion gradually becoming less sensitive and more intense from age. You may probably find a remedy in adding a little new collodion to the old; or you may find that giving a longer exposure will aid you; or the use of a developer containing thirty or forty grains of protosulphate of iron and fifteen minims of acetic acid to each ounce will tend to the production of more half-tone. The addition of about half a grain of bromide of cadmium to each ounce, and keeping the plate in the bath a little longer, will often prove a remedy.

**A SUBSCRIBER.**—We regret that we cannot point out any specific mode of proceeding. Occasionally there are advertisements in our columns seeking for such aid as you describe for India and the colonies. Failing the opportunity of waiting for such announcements, you might advertise, as the *News* circulates in India and the colonies. These are the only modes of which we know, except chance recommendation.

**AMATEUR.**—Can you find space for an additional pane of orange glass? If so, that would best meet the case. 2. Stains may proceed from many causes, but most generally dirty glasses, and long exposure and prolonged development, would much increase the risk. Have you tried giving the glass a preliminary coating of dilute albumen? 3. The statement that your negatives show a tendency to be granular is scarcely sufficiently specific to enable us to advise you. Do you mean that the surface looks granular or sandy after development, or that the texture of the finished negative is granular? If the former, it is probably because the bath is becoming supersaturated with iodide of silver, which must be removed by one of the methods we have often described, several of which you will find in detail in our last *Year-Book*. If the finished negative looks granular in texture, it may arise from slight under-exposure, and forcing in the development.

**W. R.**—The patent of the carbon process granted to Mr. Window is, we have no reason to doubt, valid. It is analogous to the powder enamel process and the process used by Herr Obernetter in reproducing negatives. Mr. Window's patent is for the application of this process to the production of prints on paper. The object of the alcohol is to aid in coagulating the film of albumen.

**A CONSTANT READER.**—The mottling is probably due to fuming the paper whilst slightly damp. We have found it occur in a much worse degree than in your example from such a course.

**NINA.**—The simplest and most satisfactory method of neutralizing chloride of gold solution is by the use of pure carbonate of lime, or "prepared chalk," as it is often named. The acetate bath gives fine purple tones if the negatives are good; it should be made a day or two before use, and need not be neutralized. It will tone rapidly if made moderately strong—say one grain of chloride of gold to four ounces of water. The silver bath is best used neutral.

**A. L.**—The first step in procuring a patent consists in depositing at the Patent Office in Southampton Buildings a provisional specification describing the invention in general terms. The cost of the Government stamp required for this document is £5. This will protect the invention for six months. If you intend to complete the patent, you must give notice within four months of lodging your provisional specification, and proceed to lodge your complete specification. The total necessary expenses of securing protection for three years are about £20, and the total further costs in securing protection for the full term of fourteen years, about £150 more. The best plan is to employ a patent agent, who will take the necessary steps and charge moderate fees for the duty.

**HAMPSHIRE.**—We are not familiar with the lens you mention. The best mode of ascertaining its capabilities will be by trial. You will find that the greater the distance between the lenses the smaller will be the field of illumination; but it will be at the same time flatter.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. THE MOST POPULAR PHOTOGRAPHIC PORTRAITS—THE BEST WAY TO VIEW A PHOTOGRAPH.

*The Most Popular Photographic Portraits.*—A practice prevails with some illustrated journals, which has of late been very much over-done, of presenting their readers weekly, or fortnightly, with a cartoon, or picture, of some great personage. *Vanity Fair* was one of the first of those which established quite a reputation for these kind of portraits, and so popular were the productions that, naturally enough, all sorts of imitations speedily arose, and now we have periodically an abundant crop of pictures, of all sorts, of great and little men. We have been treated *ad nauseam* to this literary dish, and are tired of looking at the Joneses and Jenkines that are put before our eyes because the supply of great men has fallen short: for it is only occasionally, now-a-days, that a Sir Garnet Wolseley or Albert Grant starts up. As we recently pointed out, the London *Figaro* has recently made a pleasant innovation in the matter, and taken to presenting its readers with a genuine photograph of some personage of public interest. The enterprize is a bold one, and, as far as we can judge, it seems to have been successful, although the presentation of a *carte de visite* photograph with a twopenny paper would scarcely be a paying speculation, so far as the proprietors are concerned. There is, however, yet one improvement we should like to see. The *Figaro* is of course intended to be always light and amusing, and for that reason gives its readers portraits of those people who are connected with the opera, the drama, &c.; but why not take a wider range, and give photographs of those universally loved and esteemed, whose features are rapidly fading from our memory, because they lived before photography had greatly developed itself, and their pictures are therefore comparatively rare? There is Thackeray, for instance, of whom several negatives are still in existence; but few private albums possess a picture of our admirable novelist, and a true and permanent photograph of him would be prized beyond measure in every home. And what holds good of Thackeray is true of other authors of lesser note, whether English or foreign, who have died within the last ten or twenty years. The late Prince Consort is another instance, for, although his portrait may be seen tolerably frequently, still the pictures in most photographic albums are discoloured and yellow by this time. There are probably a few Daguerreotype images of the Duke of Wellington still extant, which might be copied, and issued in this manner; and very good portraits no doubt exist of Lord Clyde, Sir John Burgoyne, and other generals of note. Then there are two portraits which, when photography plays a part, ought not to be omitted—those of Fox Talbot and Daguerre—for pictures of these two, at any rate, of the illustrious trio, are to be had; of Nicéphore Niepce, unfortunately, we have no portrait taken from life. Numerous other notabilities, now gone from us, have been photographed, whose portraits we should treasure far before those of the actors and authors of to-day, and it is sincerely to be hoped, therefore, that before the fragile glass upon which many such rare and precious pictures at present exist becomes damaged and broken, that steps will be taken to produce prints either of an unalterable nature, or images upon enamel, which could be preserved without injury for those who come after us.

*The Best Way to View a Photograph.*—Few people really appreciate the full enjoyment to be obtained from viewing enlarged photographs projected upon a screen in the same way as magic lantern slides are shown. A few days ago we were fortunate enough to attend a soirée where a most pleasant hour was spent in looking at bright representations of this kind, a No. 1B lens of Dallmeyer being the lens employed in one of the sciopicon instruments, the

petroleum flame of which, we may mention, burnt brilliantly the whole time without the slightest mishap. The first display we ever saw of this kind was at Paris, where the magnificent transparencies of Leon and Levy were projected upon a screen at one of the photographic exhibitions in that city. The instantaneous pictures were marvellously rendered in this way, one of the slides, which our readers may have seen, of a large sailing vessel being tugged into harbour by a little steamer, being most illusionary. Photographs such as these, we make bold to say, are never seen to such advantage as when enlarged and illuminated like this, for only in this way can every detail be seen; and, if possible, it is well to employ the same lens for enlarging as that originally used for securing the picture, for in this way you get rid of a great deal of the distortion which is sometimes very painfully obvious when any architectural lines are in the foreground. The pictures we saw the other night in a drawing-room were of spots from every point of the globe, and not the least interesting were some portraits of Eastern potentates on their thrones, in their State robes, which were rendered life size. It is something to be able to command the presence of this or that royal personage in one's drawing room, to be stared at and amuse the guests, who freely comment upon his awkward appearance under the trying circumstances. The easiest way to produce these transparencies is by carbon printing, because one has simply to expose a bit of carbon tissue, and develop it upon a glass plate, and the thing is done; but a dry sensitive plate will answer the purpose almost as well, only in this case great care must be taken not to print too deeply, for an image made up of silver particles will not allow the light to pass through anything like so readily as a pigment picture, although to the eye they may appear equally dense.

### GELATINE AS A VEHICLE FOR SILVER SALTS IN THE PRODUCTION OF NEGATIVES.

BY JOSHUA KING, M.A.\*

HAVING now described my method of working, which is manifestly open to the objection that the coating and drying of the plates is a difficult matter when compared with the analogous operations in the collodion processes, I must endeavour to show that there are advantages in the plan which more than outweigh these drawbacks. And first I would beg to impress upon you that you are not asked to decide that gelatine is entitled to *supersede* collodion; all that I wish to establish is that, under certain circumstances, gelatine may be used with advantage as a substitute.

The wet process will always hold its own in the studio; and there seems to be a strong reaction in its favour for field work among the most distinguished landscape photographers of the day; still there is a charm about dry-plate work which will assert its influence; and though commercial dry plates will continue to find customers, it is fair to infer that there will always be found a band of enthusiasts to whom the labour of preparing their own plates is one of love, or whose pursuits carry them into regions where they are thrown upon their own resources for the materials with which to prosecute their art. To these, I think, such a process as I have described may prove acceptable. To them it will matter little whether pyroxyline be intense or not, whether collodion be powdery or skinny, whether washing water be pure or foul; a teakettle, a tumbler, and a damp towel will distil as much water as they require in a few minutes, and a packet of gelatine will be all that they will have to carry, in the place of that dangerous travelling companion the ether bottle.

Not only will the impedimenta of the gelatine-worker be lighter and simpler than that of his fellow-labourer who prefers collodion, but it is rational to suppose that the quality of his work will be more uniform, every plate

which he prepares will be exactly like every other one of the same batch; whereas a small difference in the time in which the collodion plate has been in the washing water, or the organifier will often alter its character materially, independently of the fact that the rapid evaporation which is inevitable in hot climates forbids the hope that the last plate shall be as the first. I wish I were able to lay before you a series of plates which would worthily illustrate the process, and show that in point of technical excellence gelatine negatives are not to be despised, but I have not had the time or opportunity for negative-making since the weather became propitious. Of those which will be laid before you, one only, taken early in January last, is worthy of notice; and it is not put forward as a specimen picture or remarkable for well-timed exposure and happy development. It will, however, serve to show the characteristics of gelatine work, which seem to be softness and delicacy of detail. I would also draw your attention to a batch of failures, to each of which I have appended a note suggesting a cause and a remedy. If any members of the society who have experimented with gelatine can verify my observations, or indicate their error where I have come to wrong conclusions, I think the work of those who come after will be simplified.

The only novelty that I have imported into the process is the use of dialysis, to which I was driven in my endeavours to get rid of the nitrates which are produced by double decomposition; and I am prepared to be met by the objection that I am not obliged to have recourse to double decomposition in the gelatine solution at all. Mr. Sutton, who advocates what I may, perhaps, be allowed to call the indirect method of sensitizing an emulsion, defends his plan on the ground that he gets rid of "double decomposition within the emulsion itself, with all the attendant evils of that method."

I do not rightly understand in what the perniciousness of double decomposition consists. In the wet process the film is charged with iodide or bromide of silver by direct double decomposition in the bath; and no evil results accrue, so far as I can see. Why, then, should the same agency be condemned in an emulsion process when all the obnoxious results can be removed afterwards with little care and no trouble?

I will assume that an emulsion can be made by precipitating bromide of silver from aqueous solutions, washing it and mixing it with gelatine, equal to that which is obtained by dialysis—what advantage has the former over the latter? The preparation of the bromide of silver requires time and care. It is very liable to be attended with considerable waste, and in the end the success of the operation will depend greatly upon the energy with which the pestle and mortar have been worked; whereas by promoting double decomposition in the gelatine, as I advise, no difficulty whatever is found in procuring an emulsion of unimpeachable quality as regards absence of granulation, and neither skill nor strength are required for the simple operation which removes the obnoxious nitrates.

I must admit that my method may take a little longer, but as it does not demand fixed attention while the dialysis is in use, there need be no waste of time.

I have not tested my emulsion for free nitrate, or free bromide, but I imagine that when it is dialysed it is to all practical purposes neutral, as diffusion has abstracted all but a trace of the free salts.

The proportions of potassium, bromide and silver nitrate which I employ are, as you will observe, nearly in the ratio of their chemical equivalents. One emulsion which I made with an equivalent weight of ammonium bromide seemed to be much less sensitive than that with potassium; but whether the difference was real or only apparent, owing to unfavourable condition of light, I cannot say, as I did not repeat the experiment.

I have reason to believe that the plates will keep well; but special care must be bestowed on plate-cleaning if

they are to be kept. For a proof of this I would call your attention to a stain on a plate exposed four months after preparation, where the mark of a pneumatic plate-holder, used in India two years before, is plainly visible, though the plate had been used and cleaned at least a dozen times in the interim. The metallic marblings visible on the same plate I am disposed to refer to an abnormal reduction of the silver salt in the film, caused by a leakage of gas into the room where the plate box, which was not airtight, was kept. The plates are fairly free from blurring; and I use no backing with them, as I think that they are not liable to that form of blurring which is caused by reflection from the back of the plate.

I have said nothing about the development of the plates, as I think each worker has a method which answers well in his own hands, and that he will find no difficulty in adapting it to gelatine films. The only stumbling-block is the blistering to which I have alluded earlier; and the cause I believe to be, generally, moisture in the film. For the more subtle variety which I have indicated, I cannot at present prescribe; but I trust that its origin will be discovered, and its occurrence obviated, if the experience of successful gelatine-workers is placed at your service.

As regards the keeping qualities of the emulsion, I can say but little: I have kept it a month in cold weather without any change taking place, and the quality of the plates prepared respectively at times separated by that interval has been identical.

I do not think there is any other point in my formula which requires explanation, unless it be the addition of alcohol to the solution of silver nitrate. I adopted this addition upon the recommendation of a gentleman signing himself "Ostendo non Ostento," who wrote on the process in the *British Journal* last autumn, and I find that I can get a fine emulsion, free from dots, more easily when I use it than when I substitute water. I cannot trust myself to explain what I regard as a fact, so as to satisfy those whose knowledge of the mechanical condition of the alcoholic solution may convict me of empiricism; but if precipitation is to some extent retarded by the different density of the two menstrua, I venture to submit that I am justified in believing that the precipitate is more finely divided.

In conclusion, I need hardly remind you that in dealing with subjects in which physical science is the arbiter, I am venturing into a region which the feet of the uninitiated can hardly tread without stumbling; I must therefore beg you to excuse the crudity of my opinions on the ground of inexperience, and to pardon the length of these remarks in consideration for the garrulity of an enthusiast.

#### UPON THE SENSITIVENESS OF THE SURFACE OF TINTED BROMIDE OF SILVER TO THE DIFFERENT COLOURS OF THE SPECTRUM.

BY DR. D. VON MONCKHOVEN.\*

Presented by J. H. DALLMEYER, F.R.A.S.

IN the month of December last I became acquainted with the researches of Dr. Vogel upon the sensitiveness of dry plates to the red and yellow rays of the spectrum. According to Dr. Vogel, a plate prepared with bromide of silver is sensitive only to the rays of the spectrum more refrangible than the green; whilst, if the bromide film is coloured yellow or red, it becomes sensitive to the yellow and red portions of the spectrum at the same time.

M. Vogel goes so far as to lay this down as a general law. He affirms that by adding to the bromide of silver any colour which absorbs a certain part of the spectrum, the maximum of sensitiveness in the bromide will be found in this portion.

For some years past I have occupied myself with spectrum observations, with the object of determining by photography the coincidences of the ultra-violet rays with the brilliant rays of metals and gases. I have

\* Read before the Photographic Society of London.

moreover, sought means to establish these coincidences in that portion of the spectrum visible to the eye: but all my efforts have hitherto been in vain to obtain photographic reproductions in the green, yellow, orange, and red.

I was, therefore, in a great hurry to employ the method indicated by Dr. Vogel; unfortunately, however, it was only during the last few weeks that I have been enabled to establish my apparatus satisfactorily. Another motive I had for repeating the investigations of Dr. Vogel was this: we know that all opticians, when they desire to construct a lens free from aberration for the chemical or actinic rays, always start with the assumption that the maximum sensitiveness of our photographic films is to be found near line G in the indigo portion of the spectrum. Now, if this maximum be displaced—as would have been the case upon the coloured surfaces of Dr. Vogel—there would be no plan of rendering an objective free from aberration in the above sense for all photographic processes alike.

Thus, a lens exempt from aberration for the ordinary collodion process would have a considerable amount of aberration when used with bromide of silver tinted red, yellow, &c. It became a matter of urgency, therefore, to thoroughly establish the soundness of Dr. Vogel's discovery, and I desired to do so with the most perfectly constructed apparatus.

The description of apparatus I employed was as follows:—At A was placed a heliostat, Leon Foucault's

construction, having a silvered mirror which reflected the rays in a horizontal direction. In the path of the solar beams I placed a condenser\*, five centimetres in diameter, and 90 centimetres focus. The solar image was thrown upon the slit C of the spectroscope formed by a collimeter

(C D) of 18 inches focus. The dispersion was obtained by four large prisms, of 45 degrees, made of Chance's extra-dense flint glass. The lens of the spectroscope was replaced by a lens (I) of 90 centimetres focus, mounted in a bellows camera. The image (L M) of the spectrum is received upon a moveable plate in such a way that one may secure several impressions upon the same plate.

By reason of the considerable dispersion of the four prisms, it was impossible to obtain the whole of the spectrum upon one plate.\* Besides, focussing would be impossible, as every portion of the spectrum has a corresponding different focus. The spectroscope which I have just described is, in other respects, identical with that of Kirchoff. It may be seen from the negatives which accompany this memoir that all the rays marked upon the spectrum of Kirchoff, even the finest, are here reproduced. This fact, I think, will be taken as a standard of the precision with which I have worked.

My friend, Mr. Dallmeyer, will, moreover, exhibit to the members of the society a photographic reproduction of the Kirchoff spectrum which I have produced expressly, and another image of the spectrum which I owe to the kindness of Mr. Rutherford, of New York, obtained direct by photography, and upon which I have marked all the corresponding lines of Kirchoff.

When a wet collodion plate is exposed in the spectroscopic apparatus which I have just described (the opening of the slit being 1-30th of a millimetre) for a brief period—five seconds, for instance—a spectrum B is obtained, limited to the indigo. I have focussed this portion of the spectrum with particular care, and every one may see the absolute clearness of the lines, the finest corresponding to portions 2700 to 2870 of Kirchoff. To do this it is necessary to place the plate against a well-lighted ground glass, and to employ a powerful magnifier.

The maximum sensitiveness of our plates for the solar spectrum is in the indigo. The same plate being submitted to an exposure in the apparatus for two minutes (see Plate I., spectrum A), the action extended on one side to HH' and on the other to E. But the clearness of the rays disappeared by a phenomenon analogous to irradiation. The lines spread on account of excessive development. Moreover, the focus having been made at G, all the other lines lack clearness.

In Plate II., line F was focussed; it carries three spectra, the first (C) exposed for four minutes, the two others twenty seconds. Upon this plate can be seen clearly in spectrum C all the lines comprised between G and b, and the image extends to beyond E, to 1450 of Kirchoff.

I experimented with other wet collodion plates, but, notwithstanding a prolonged exposure, I was unable to get beyond the limit of 1450 in the Kirchoff tables. Plate III. was focussed upon lines bb', and shows with exceeding clearness all the lines of Kirchoff from 1660 to 1450. These last lines are wanting in Rutherford's spectrum, the latter, no doubt, not having employed a condenser.

Plate IV. represents two spectra obtained upon bromide of silver alone, without iodide in the collodion. The lower half of the plate has been submitted in the first place to the action of weak daylight for a few seconds. This last carries the spectrum H, the upper part of the plate the spectrum G. Each image has been exposed two minutes in bright sunshine.

This plate shows all the lines clearly, and proves that bromide of silver, employed in wet collodion, is not more sensitive to green than iodide, for the impression is identical with that of Plate III.

Finally, Plate V. is prepared with collodion containing a little coralline to tint the film red; and as I am entering here upon Dr. Vogel's experiments, I will detail my plan of working.

The collodion contains two per cent. of the double bromide of cadmium and ammonium; the silver bath was of

\* The object of the condenser is to give the spectrum a much greater degree of intensity than that possessed by direct solar rays only. The clearness of the rays is in no way affected if the opening (that is to say, the relation of the diameter to the focal length) of the condenser be less than that of the lens of the collimeter, and the prisms be of sufficient dimensions.

\* The total length of the spectrum was more than forty centimetres.

eighteen per cent. strength, and the plate was immersed for ten minutes. The plate was exposed for five minutes to the action of the spectrum, the focussing being made at E. The development was conducted with iron in the ordinary manner. I imperfectly fixed the plate, which is still red with the coralline it contains. An examination of the image shows that it is perfectly defined between H H' and E. But it is evident that not a line has rendered itself visible in the yellow and red. In one word, the plates tinted with coralline and the untinted ones are identical. The same result was obtained with aniline green.

I then tried a dry plate produced with bromide of silver, placing in the preservative, coralline, Bismarck yellow, fuchsine, &c. In a word, I varied my experiments in every possible way, and in none of them did the image transgress the limit of 1450 of Kirchoff. Indeed, on some of these plates I obtained no image at all.

I also experimented with coloured papers, but without any result.

I must confess that these negative results have filled me with surprise. Nevertheless, if my information is correct, in Bunsen's laboratory at Heidelberg no results also have been obtained. I have just received a letter from an illustrious French physicist who also tells me that he has obtained no results at all. From the Ecole Normale, and the Conservatoire des Arts et Metiers, in Paris; from Mr. Norman Lockyer, Mr. Spiller, and Colonel Stuart Wortley, in England; and Mr. Carey Lea, in America, the same negative results are reported. Therefore I conscientiously believe Dr. Vogel to be in error. An attentive examination of Dr. Vogel's memoir and my own results may, perhaps, be instrumental in discovering the origin of the error in which our estimable author has fallen.

Dr. Vogel affirms that the colours of the spectrum are absolutely pure. This is true in theory, but not so in practice. In the first place, I remark that Dr. Vogel uses a slit of a quarter of a millimetre in width, and only one prism of flint glass. This slit is ten times larger than those which are ordinarily employed, and does not allow one to see the lines of the spectrum with clearness. Besides (and this is an essential point) the glass prism is not absolutely transparent, and diffuses rays of every refrangibility over the whole photographic surface. Finally (and this applies especially to apparatus of several prisms), as the pencil of rays refracted by the prism has a large angle of divergence, it always happens that a portion of the red is reflected upon the interior wall of the tube of the eyepiece when the violet is under observation, and the violet is reflected when the extreme red is being observed. This is why coloured glass is always placed in front of the slit by Kirchoff and others. If the red is being examined—especially in the neighbourhood of line C or A—a red glass is employed; or if it is the violet, then a violet glass is placed in front.\*

To convince the members of the society of this phenomenon of the diffusion of light over the whole surface of the photographic plate, I produced plate G with a direct-vision spectroscopic composed of five prisms, equivalent for dispersion to two prisms of flint glass of 60°. It is understood I have employed a small slit one-twentieth of a millimetre to render all the lines visible.

The upper spectrum was obtained in five seconds. It is limited by the blue and indigo. The spectrum in the middle has been exposed for one minute, the lowest for ten minutes. It reaches beyond the violet and red. When one is not on one's guard, it seems as if the whole spectrum has been obtained; but it is only the diffused light which illumines the prism that has acted, and the proof of this is, that neither the vertical lines which characterize solar

light, nor the long horizontal lines which come from the shutters of the slit, are visible in these parts of the spectrum. The spectrum of one minute and that of ten are in reality alike.

I am quite convinced that Dr. Vogel's plates do not show the double line D, nor the line C, nor the lines B and A of the solar spectrum. To obtain these lines with all the clearness of Fraunhofer's spectrum, only an ordinary spectroscopic is necessary, with one flint prism of 60°. But the slit must be narrow—for instance, about 1-20th of a millimetre. Neither, as has been affirmed by Dr. Vogel, is the bromide of silver, coloured red with coralline, so sensitive to the yellow and to the red as it is under ordinary circumstances to the blue and the indigo with a ten seconds' exposure to the solar spectrum. For, under these circumstances, in ten seconds I obtain the violet, indigo, and blue, with several hundreds of lines, upon a dry bromide plate.

If Dr. Vogel would expose in an ordinary spectroscopic, with a narrow slit, one of his plates for only a few seconds towards evening, he would find that he would obtain a splendid spectrum with all the lines of the solar spectrum, together with other lines due to absorption of atmospheric moisture.

The publication of a spectrum by photography in one of the journals is the most practical plan for Dr. Vogel to pursue in order to decide whether he has discovered a new process or not; for a photographic spectrum of these regions of the spectrum would be a proof beyond cavil of the results stated to have been obtained by him. All other arguments would be valueless against this.

At the same time, as Dr. Vogel promises, in reply to Mr. Spiller, to publish his method of proceeding in every particular, in Poggendorf's 'Annalen,' I propose, as soon as they are made known, to follow them accurately, and publish the result.

#### HOW TO MAKE A POCKET CAMERA.

W. J. LANCASTER, F.G.S., ETC.\*

This apparatus consists of three parts: the camera, with its three double dry plate slides; the lens; the stand. In the first place we must describe the camera. This consists of a bellows body made of a strip of leather measuring 17 in. by 6 in.; this is glued end to end so as to make a hollow square measuring 4½ in. broad, and 3¼ in. high, being, of course, 6 in. long. The next process is to bend the corners so as to be able to fold the bellows. In the bellows of my camera we put five folds, the first, third, and fifth being bent down, and the second and fourth being bent upwards, so as to occupy smallest space possible. Let us assume, therefore, that a bellows is made which when folded measures 4½ in. by 3¼ in. by ½ in. Now stretch bellows out to full extent and glue into the inner surfaces a thin dead black linen; put bellows by for two or three days until glue is perfectly dry before attempting to mount it. Now, for making the front of camera, get a good piece of well-seasoned mahogany measuring, when planed, 5½ in. by 4½ in. by ¼ in. in thickness, also two strips of good mahogany 4½ in. by ¾ in. by ¾ in., and two 5½ by ¾ in. by ¾ in. These must be dovetailed together to make the framework to hold front on; they must have pieces of brass at each corner, clamping corners, and screwed into sides with small brass screws. The front piece must be planed down on back side for one inch all the way round to a thickness of ¼ in. This is on purpose to make the instrument more portable than it otherwise would be, at the same time leaving a space 3½ in. by 2½ in. in centre of front, having a thickness of a quarter of an inch, for the flange of a lens to be screwed on to, giving a good hold to screws. The front is now to be screwed and glued on to framework; we use about a dozen ¼-in. brass screws, three on each side. This gives to the front a firm appearance, and, although light, yet it is very strong. The

\* Or between the eyepiece and the eye. The eyepiece in photographic observations is the sensitive plate; therefore it is better to place the coloured glass in front of the slit.

\* We slightly condense the above article from the *English Mechanic*.

bellows must be glued on to the back of the front, care being taken to completely glue the bellows all the way round, so as to prevent the smallest possibility of the ingress of light. The back portion of camera consists of a framework measuring  $5\frac{1}{2}$  in. by  $4\frac{1}{2}$  in. by  $\frac{1}{2}$  in., dovetailed and clamped with brass similar to the portion behind front board. This framework is a little deeper than front part, because of having to take the other end of bellows; the clear inside of back part is  $4\frac{1}{2}$  in. by  $3\frac{1}{4}$  in., and a depression is made in the front portion of this frame for gluing hinder part of bellows. Having now made skeleton part of camera, glue bellows to front part and also to back, so as to fold easily, and to measure, when folded, one inch. Then put a screw into back part on each side, and a small hook to clip on to screw, so as to keep two portions together when carrying.

Now as to the provision for holding slides. The back part of camera has two brass strips screwed on vertically, for slides to go up and down easily. The brass pieces are  $4\frac{1}{4}$  in. long,  $\frac{3}{4}$  in. wide, and about as thick as a worn threepenny piece. These strips are screwed on to each side with four brass screws. The tops of the strips are slightly rounded, so as not to break edges of slides when slipping up or down. At the top, across the camera, where slides move over, there is a narrow strip of black velvet, to prevent the passage of light down on to plate.

There is just one more particular to mention about camera: that is, the method of holding it when stretched out. This, of course, may be accomplished in many ways; a folding tail-board may be used, but this makes camera a  $\frac{1}{4}$  in. thicker when closed, and several ounces heavier for carrying. I have tried many methods, and have adopted the following, namely, a strip of brass 6 in. long and  $1\frac{1}{2}$  in. broad, and about as thick as a shilling. It should be made of hard metal. About  $1\frac{1}{2}$  in. from one end a nut is soldered on, with an inside thread to screw on to stand; in the end nearest to this screw make two holes as wide apart as the metal will allow: the holes to be about  $\frac{1}{8}$  in. diameter. These are for the purpose of holding camera front by means of two thumbscrews, the screws screwing into a brass plate, which is permanently fixed to bottom of camera. From the screws for stand to within  $\frac{1}{4}$  in. of other end of brass plate a slot is cut  $\frac{1}{4}$  in. wide, and on to the bottom of back portion of camera a brass plate is screwed with a projecting piece  $\frac{1}{2}$  in. by  $\frac{1}{4}$  in.; this is made to slide easily, and yet firmly, in the slot of brass plate. There is a screw which binds the plate to back of camera at any given point, according to focus of lens. Upon the top of camera put two small screws like battery screws, allowing a stocking-needle to pass through them, the needle being broken to suit greatest length of camera when drawn out. It will be evident that the camera can be made to swing either backwards or forwards by means of this needle and loosening of the screw underneath back of camera. Having now finished our camera, we must next turn our attention to the dark slides.

First, let us construct the ground glass slides. Take two strips of mahogany  $\frac{1}{4}$  inches long,  $\frac{1}{2}$  in. wide, and  $\frac{3}{8}$  in. thick; these are for the two sides of slide; then two slips of mahogany  $5\frac{1}{2}$  in. long,  $\frac{1}{2}$  in. broad,  $\frac{3}{8}$  in. thick; these are for top and bottom. They must be mitred at the corners, and a groove made on one side to hold a piece of ground glass  $4\frac{1}{4}$  in. by  $3\frac{1}{4}$  in.; the glass sinks into frame to its own depth, and is held down by four brass strips, one at each corner of the ground glass, screwed on either side of slide. The edges of this slide may be grooved, so as to slide down the brass works at back of camera; or the frame may be made small enough to slip through space between brass plates on back of camera, and in this case the focussing slide could be hinged on to top of camera, so that it could be bent over top of camera when exposing a plate. The dark

slides are the most difficult part of apparatus an amateur can attempt. The double dry-plate slide consists of two halves exactly alike, and hinged at bottom of each slide; the size of slide when upright is  $5\frac{1}{2}$  in. long,  $4\frac{1}{4}$  in. high, and  $\frac{3}{8}$  in. thick, each half, of course, being 3-16 in. thick. Each half consists of a framework similar to frame for focussing slide, and is made of two strips of mahogany for sides  $4\frac{1}{2}$  in. long,  $\frac{1}{2}$  in. broad,  $\frac{3}{8}$  in. thick; the bottom strip is  $5\frac{1}{2}$  in. by  $\frac{1}{2}$  in. by  $\frac{3}{8}$  in.; the top piece  $5\frac{1}{2}$  in. by  $\frac{1}{2}$  in. by  $\frac{1}{2}$  in. thick; the  $\frac{1}{2}$  in. taken off is to allow slide to move up and down. The four pieces are fastened together exactly in same manner as focussing slide, and have a space to hold a glass  $4\frac{1}{4}$  in. by  $3\frac{1}{4}$  in. in their inner sides, the outer sides having a groove from top to bottom to slide down brass strips on camera. The movable slide for exposing plate moves down a groove immediately in front of part to hold plate; this slide can be made of a piece of mahogany  $4\frac{3}{8}$  in. by  $3\frac{3}{8}$  in. by  $\frac{1}{2}$  in. thick, or can be made of tin or any metal same size as above. These slides are better when made in two pieces, and fastened together by a strip of leather, the hinge thus made being useful in preventing the side slipping down when exposing a plate, and also preventing any light passing through space between camera and slide; at the bottom of this slide there is a narrow strip of wood, stretching across from side to side, to prevent the photographer pulling the slide completely out of dark slide. On the top part of the dark slide are two small pieces of brass, movable round a screw; these keep the movable slides down when carrying, and by tuning the piece of brass round the slide is free, and can be raised. Supposing the two halves of the dark slide to be made, we must then devise a method of opening and of fastening them together when closed. This proved a slight difficulty to me when making the cameras in their present extreme portability; and, after many experiments, I made a small fastener on top of slides, which acts simply and well. A piece of brass  $\frac{1}{2}$  in. long, and  $\frac{1}{4}$  in. broad, and 1-40th of an inch thick, has a hole drilled through one end, and a slit filed in other end. The piece is screwed down on to one half of slide, and a screw is screwed on to other half of slide, so that when closed the piece of brass is pushed along, till the slit closes over screw, and holds them together. I put two of these small plates one on each side of the top of slide. The hinges are at the bottom of the slide, and each half of hinge is let into the corresponding half of slide, thus causing slide to touch in every part. But we have not yet made slide light-tight. This is easily done by making a groove all round one half of slide, immediately outside part for holding glass, and gluing strips of wood on other half, so that when closed the strips would push into grooves, and prevent the entrance of light. The movable slide has a piece of leather glued on to front surface at the top part, to enable one to lift it up.

YORKSHIRE EXHIBITION OF ARTS AND MANUFACTURES.—An exhibition in connection with the Leeds Mechanics' Institute and Literary Society, and Schools of Art and Science will be held in 1875, to open on the first of May. The object of the exhibition will be to promote the fine arts, and art and science as applied to manufactures, and the surplus funds will be applied to the liquidation of the debt now remaining on the Leeds Mechanics' Institute. Subject to the necessary limitation of space, all persons, whether designers, inventors, manufacturers, or producers of articles, will be allowed to exhibit, but they must distinctly state the character in which they do so. Prices may be affixed to the articles exhibited, and sales effected; but articles once deposited in the building will not be permitted to be removed without written permission from the Building and Space Committee before the close of the exhibition. The classification of the exhibition will be as follows:—Department I. Arts and Manufactures.—Department II. Fine Arts, including paintings in oil and water colours, and drawings; sculptures, models, die sinking, and intaglios; etchings and engravings; antiquities; photography.

### PRINTING FROM TWO NEGATIVES.

IN a recent article on Denier's method of producing prints of peculiar softness and fine modelling, which qualities were due, as we were enabled to state, to the use of two thin negatives, one placed behind the other, we pointed out the powder process as best suited for the production of such duplicate negative. The same idea as to the application of the powder process to such purpose had, it appears, occurred independently to Mr. B. J. Edwards, who at the last meeting of the South London Society exhibited a result obtained by this application. He showed a print obtained from a good thin, sharp negative, and a print from the same negative with a duplicate negative image placed behind it. The latter was decidedly an improvement upon the first, although the first was an unusually fine picture. The print obtained when the light traversed two negatives had, as in Denier's portraits, a peculiarly rich, solid, and artistic quality. Whilst there was perfect definition as to the result of the contact negative, there was a peculiar fullness of modelling, and a singular softness without fuzziness, produced by the light passing through the negative not in contact.

In Mr. Edwards' experiments, he had placed both the negatives on one glass, the duplicate being on the back of the glass containing the original negative, in manner similar to the duplicate negatives we described some time ago, obtained by coating both sides of the glass with collodion, and producing the duplicate image in the camera. Mr. Edwards coats the back of his negative with the bichromated syrup, and exposes the front to parallel rays, so as to secure a moderately sharp image by printing on the sensitive film through the glass. We presume that the exposure must be a full one, as the light impinging on the under side of the bichromated film must pass quite through it in order to give a satisfactory image, and admit of developing by application of the powdered plumbago. It seems probable that a better plan would be to take the duplicate negative in the ordinary way by the powder process, upon a separate glass, adopting the plan, however, mentioned by Mr. Woodbury in our last, of giving the glass a preliminary coating of collodion. The completed duplicate negative being, after transfer, contained between two layers of collodion, may be used in that form without a glass support. It may then be used in any position the photographer may choose, either at the back of the original negative, or in contact with its face, or with some thin medium interposed, so as to modify the effects to be produced. In producing the duplicate negative on a separate support of thin tissue, rather than at the back of the original negative, other advantages are gained, and inconveniences avoided. In case of failure in deciding the right exposure, the duplicate on a separate plate is more easily examined than when it is in inseparable contact with the original, and

less trouble and risk are involved in repeating the operation, in case of failure of any kind, with a separate plan, than when the plate used is the original negative itself. Although Mr. Edwards assures us that there is no trouble or danger to the original negative in submitting the duplicate at its back to the necessary washings, many photographers would, we imagine, prefer not to incur the possible risk with a valuable negative.

As the powder process allows the production of duplicates which vary the effects of the original, permitting the operator to secure excess of detail or excess of contrast at will, and permitting, even, of variations in the light and shade of the background, by applying the plumbago more persistently in some parts than in others, it is manifest that considerable scope to the artistic taste and skill of the photographer, in producing and printing from his duplicate negative in contact with the original, is offered in this process. A recent letter from M. de Constant indicates the collodio-chloride process as the method employed by M. Denier in obtaining his duplicate negatives. M. de Constant thinks the results obtained by M. Denier so exceedingly perfect and charmingly artistic, that he suggests to us the wisdom of inducing a number of English portraitists to combine to purchase all the details of the method. It is manifest that the collodio-chloride process presents facilities for obtaining very perfect duplicate negatives; but the powder process, we are bound to admit, presents simpler facilities, with a wider range of modifying power; and to all who feel interested in experiments in artistic printing we commend a plan which in trouble costs so little, and in result promises so much.

### LAWS OF THE PHOTOGRAPHIC SOCIETY.

THE new draft of laws is now in the hands of the members of the Photographic Society, and a special meeting will be held on the 30th instant, for the purpose of considering, and, we presume, adopting them. The chief difference between the draft laws just sent out, and the old laws, which have been in force for so many years, consists—besides securing more precision on many points—in the conditions of office and the mode of election. The chief difference between the present draft and that sent out about three months ago consists in brevity, the present draft comprising eleven laws, whilst the draft of March consisted of twenty-five sections and seventy-six clauses, involving, in the aim at precision, an excessive amount of detail which was calculated to defeat its end, and issuing in prolixity rather than clearness.

The first noticeable point in the new draft is the title of the society, which is changed from the "Photographic Society of London" to the "Photographic Society of Great Britain," and thus is heralded, we presume, the aim which is afterwards apparent in the laws, to give a more national character to the society by invoking the action of country members in all vital matters concerning the interests of the society. The tenure of office is modified. The office of president, instead of being for life, as under the old system, is now proposed to be the subject of annual election. Whilst, however, the president will retire annually, he will always be eligible for re-election, so that whilst an inefficient president need not be retained longer than one year, an efficient president may be retained in perpetuity; and whilst these advantages are gained by the society, a higher honour is paid to the president who is re-elected year after year, than could be involved in the continued retention of office without re-election. Of the three vice-presidents, one must retire annually, in the order of seniority. This perpetuates the old law; but with the difference that formerly the retiring vice-president was eligible for re-election to the same office; now, whilst eligible for election into other offices, he will not be at once eligible for re-election as vice-president. Six members of the council will retire annually, but they will be eligible for

re-election. This leaves the absolute control of the matter in the hands of the members themselves. If it be their will that an infusion of new blood into the council, to the extent of one-third of its constitution, be desirable, they will have the power to elect six new members; but if, on the other hand, they find amongst the six members of council retiring in the order of seniority some gentlemen whose services they deem it important to retain, then the eligibility for re-election removes any bar to such retention. Laws should never trammel the body for whose government they are made, nor prevent them doing anything which, *per se*, they have a right to do; and a law which should say, "You shall not re-elect certain individuals to office, however desirable it may be for the interests of the society to do so," would so trammel the members, who, in a body possessing comprehensive voting powers, should have the right to say by their vote at any time what is the best thing to do at that moment.

The voting for the election of officers is to be the work of the whole society—not simply the privilege of a few metropolitan members—and the duty of nominating officers for election is also delegated to the entire members, instead of being confined, as some have proposed, to those members who chanced to be present at a meeting preceding the annual meeting. Every member of the society will be at liberty to nominate as many officers as there are vacancies, by writing in proper time to the secretary, and every nomination, together with the names of retiring officers who are eligible for re-election, will be printed on voting papers and sent to every member of the society, with instructions as to how to deal with them, striking out all names but those for whom he may desire to vote. The voting paper thus marked will be returned to the secretary in an envelope sent for the purpose, and of a character which will identify its contents as a voting paper. This envelope, being delivered unopened to the scrutineers appointed by the meeting, will carry out all the aims of the ballot, as the papers will be unsigned; and whilst precautions are taken to avoid a paper reaching any hands but those of a member, equal precautions can be taken to avoid identifying the voting paper received from any member. Such is the plan of voting proposed, and it is, so far as we can see, free from any form of objection. The nomination in open meeting which has been advocated by some is here superseded by a plan possessing all the advantages, without any of the disadvantages, of the other method. Nomination in the meeting is a plan open to many objections. It is an unnecessary waste of time; it limits the privilege of nomination to members present in the meeting; and it is offensive and invidious. Just in proportion as it may be considered an honour to be elected into the council, it might become a reproach to be publicly and demonstratively proposed, and then fail to be elected; whilst the written nomination would render defeat a much less obtrusive annoyance.

A variety of minor points of change of law, are made in the draft just sent out, the precise bearing of which will be best seen by comparing the draft with the old laws. The main changes refer to the election of officers, and an important clause is added to Rule XI., having reference to changes in law at special meetings. In the draft it is laid down as a condition that no change in the laws can be effected without the consent of the society at large, every member having the right to vote on such questions. Such a provision will prevent serious changes being effected by small majorities in special meetings, and entirely obviate the possibility of misunderstandings similar to those which have recently disturbed the peace of the society. It destroys, in fact, the power of faction: small combinations to effect a given purpose in a special meeting will henceforth be useless, as a majority of the members alone can affect any vital change in the constitution or the executive of the society.

#### ARTISTIC ARRANGEMENT OF GROUPS.

"THE first thing I look at when I have a group before the camera," Mr. Rejlander once remarked, "is the outline of the picture it produces. The filling in may be considered next; but it is of imperative first importance that the outline should be right, and form a picture." As a rule there is no task more diligent to the portraitist than the management of a group. In order to secure something of pictorial effect as well as likeness, the figures must be arranged so that they will compose well, and give a satisfactory balance of lines and masses. Then they must be all in focus, and there must be something of variety in arrangement of the various figures. The mechanical difficulties are serious enough, and must be met as they arise; but it is important to have some definite artistic ideas as a primary condition of pictorial success. Here are a few valuable hints, the remembrance of which may be useful, contributed to our Philadelphia contemporary by Mr. Bigelow, whose album of lighting and posing is well known. Mr. Bigelow says: "It is difficult to apply art rules in making up photographic groups, from the fact that in art compositions there is one or more central or important figures to which all the others are secondary and supporting; while in photograph groups for portraiture all are supposed to be of equal importance, and individuals must not be slighted pictorially, or the sale of the picture is assuredly lost; for this or that figure is not as good as its neighbour. In genre compositions of course we are not limited in this direction, but our greatest obstacle is to group our subjects in such manner as to gain perspective, and overcome the appearance that they are placed in a line like soldiers on dress parade. I know of no way by which perspective may be obtained better than by placing in the foreground low objects or pieces of furniture which tend to break up the line appearance, and also give depth to the picture. All ambitious photographers should know what constitutes angular, pyramidal, and circular grouping, for otherwise many mistakes will be made which this knowledge would have prevented. Special attention must be paid to side lines, or those lines which run parallel to the sides of the picture. Break these lines all you can. For instance, if a chair is placed near the margin of a picture, set it with the back toward the centre; or if turned the other way, be sure to set some lower object between it and the margin, and near the chair, which you at once see breaks up the effect of parallel lines formed by the back of the picture and the margin line. If a curtain were draped just back of the chair, it would do just as well to break the lines mentioned. The lines of a curtain should be draped from the margin toward the centre of the picture, and so in principle must be the arrangement of all accessories in photography, portraiture or grouping."

#### FRENCH CORRESPONDENCE.

Of the eighty-four exhibitors this year at the Photographic Exhibition at the Palais de l'Industrie, twenty-three have forwarded specimens of carbon printing, printing in greasy ink, photo-lithography, photo-engraving, enamelling, &c.; in one word, examples of processes in which the employment of silver salts is excluded. At the last exhibition, in 1870 there were but sixteen exhibitors of these kinds of photographs out of one hundred and nine. From fifteen per cent., therefore, the proportion has been raised to thirty per cent. Moreover, it must be pointed out, that of the exhibitors of 1870, many had sent pictures merely as the results of trials and experiments, whereas those exhibited at the present time are for the most part specimens of processes in actual working order, or which are being employed industrially.

For a long time M. Lafon de Camarsac was the only producer of enamels in France, and after him came M. Mathieu Deroche. This year we find, besides the latter, MM. Gougenheim and Forrest, Mdlle. Mezzard, M. Piel

Peehardière, MM. Geymet et Alker, and M. le Comte de Roydeville. Not only are M. Lafon de Camarsac's rivals at the present day very numerous, but the productions that they exhibit are quite worthy to compare with his. There is progress to be observed everywhere in the application of the colours, and the paintings on enamel which these artists show the public are, in fact, very pretty miniatures.

As regards printing in carbon, M. Braun still enjoys the first place among the exhibitors. He has so overcome the difficulties of this process that he seems capable of producing pictures of any dimensions. Among the pictures he exhibits, there are some measuring not less than a metre square, and which, nevertheless, are without even the slightest defect.

As to other exhibitors who have sent work of the same kind, their number, artistic qualities, and variety, prove to the most sceptical partisans of routine that this method of printing is quite as practical as that of silver salts.

Many well-known photographers occupying themselves with carbon printing—MM. Gobert, Jeanrenaud, Fargier, Soulier, Piot, Marion, &c.—have abstained from exhibiting on the present occasion; otherwise the proportion we mentioned at the commencement of this letter would have been more considerable. It is an obvious fact, therefore, that the new processes have been very extensively developed during the last year or two.

As regards heliographic engraving, M. Rousselon is developing upon a large scale, for MM. Goupil and Co., a most beautiful process, of which we have already spoken, and which has gained for him this year a *medaille d'honneur*. In another direction, MM. Lefinan et Lourdel, as also MM. Yves and Barret, furnish daily to illustrated journals a considerable number of typographical blocks by means of photography, the processes having a good deal of analogy between them. A design of any kind is given—whether a page of manuscript, an old engraving, &c.—and in the space of forty-eight hours they return a block engraved in relief, representing the original in every detail, either of the same dimensions, or reduced or enlarged, as the case may be. The blocks are ready for printing in any printing press; and although some years ago their production would have been looked upon with wonder, they are now produced at the rate of fifteen centimes (three halfpence) the square centimetre.

It may be imagined with what eagerness editors of illustrated journals, and such like publications, profit by the advantages of this process, and the firms to which we have alluded can scarcely supply the large demands made upon them.

With regard to a letter published by M. Quiquerez in the *Moniteur de la Photographie* of the 19th May last, I have just received from M. Thierré some remarks about his method of sensitizing albumenized paper. M. Quiquerez expressed some doubt respecting the advantages of adding alcohol to the silver bath, and M. Thierré essays to dissipate such doubt, not to sustain his reputation as an author, but because long experience in the matter has confirmed him more and more in the view he advocates. M. Quiquerez says that the dry albumen is not coagulated, to which his opponent replies: I have tried carbon printing, and for my support I employed albumenized paper, not salted, which was sometimes coagulated by means of alcohol, and sometimes by the aid of hot water. In both cases I obtained complete coagulation of the albumen. Other substances, such as bichloride of mercury, nitrate of silver (and it is this only that is employed for sensitizing, in the form of a twelve or fifteen per cent. solution), coagulate dry albumen, as all the world knows.

Our correspondent moreover remarks that M. Quiquerez himself proposes to coagulate salted albumenized paper by immersing it in alcohol before sensitizing it upon a silver bath. M. Thierré raises two objections against such a course: in the first place, he employs one operation instead

of two; and, again, his method is more economical, which consists in adding to the silver bath a relatively small proportion of alcohol, sensitizing and coagulating the paper at the same time. What proves, according to him, that in this process the coagulation is complete, is the circumstance that the bath is never discoloured, and it is never necessary to expose it to the light. He adds, that for the last three weeks the temperature in his studio has been 20° Cent., and although his bath has not been refreshed during the time, the solution has not become tinted, which is a proof that it contains no organic matter.

As to ammonia fuming, which is generally used with advantage when a weak bath is employed, it is not necessary when the albumen is coagulated by an alcoholic silver bath. M. Thierré has made the experiment, and found that the only advantage was an increase in the rapidity of printing; but the toned and fixed print under these circumstances had not such a nice tint as usual. It may be added that M. Mevins, the skilful English photographer established at Rennes (Ille et Vilaine), whose acquaintance I had the pleasure of making during a recent journey to Paris for the purpose of acquiring the sole license for Lamberttype in the district where he lives, told me that for years he had only employed alcoholic silver baths, and had found them exceedingly satisfactory.

I profit by this occasion to return my thanks to Mr. Davies for his communication, through the PHOTOGRAPHIC NEWS, relative to the existence in commerce in England of coagulated albumenized paper. This is an example which our manufacturers will make no difficulty in following.

M. Sutton has just communicated to me that he has published in my journal a process termed "Coloured Carbon Enamel," which allows one to obtain very easily a new kind of portrait which will certainly give satisfaction to the public. The resumé of the process is as follows:—A sheet of carbon tissue is taken and sensitized by plunging it for half a minute in an almost saturated solution of bichromate of potash. After drying in the dark, it is exposed under a cliché for a third of the time necessary to produce an albumenized silver print. The tissue is then immersed in a bath of cold water, and applied to a glass plate. After a few seconds, the plate upon which the tissue adheres, face downwards, is put back into the bath, and a squeegee passed over it to make contact more perfect. It is then removed to warm water, and the image developed upon the glass plate: the portrait is then painted on the back, using opaque oil colours for the purpose, which are applied with a very soft brush. It is necessary that the colours should be perfectly opaque, in order to penetrate the image, and afford a backing to it. This mode of painting is identical in principle to the Neoleopainture which I described a little while ago; it does not interfere with the details of the picture, nor destroy the likeness in any way.

ERNEST LACAN.

## PHOTOGRAPHY FROM A SANITARY POINT OF VIEW.

BY DR. H. NAPIAS.\*

*General Aspect of a Photographer's Work.*—We may commence this subject by saying that there is nothing in a photographer's every-day work that is of a nature to be prejudicial to health. There are, for instance, none of those movements incessantly repeated, none of those constant performances to be met with in other professions, which so often become the source of maladies and deformities. Nevertheless, those occupied with retouching, labouring at a work which tells upon the eyesight, may experience a tiring and weakening of the eyes. Retouching of negatives, especially, may occasion some physical troubles.

The evil is also met with in the case of photographers who prepare tiny microscopical impressions, either for scientific purposes, or as curiosities to be put in a piece of

jewellery or on the head of a stick. A photographer who was under my care, and who, during the late war, was attached to the photographic service occupied with the reduction of microscopic despatches, had his eyes in a state of congestion in the centre of the orbits, together with chronic inflammation round the eyelids. This photographer, who still occupies himself with microscopic photography, noticed that the inflammation became worse every time he fatigued himself a little more than usual, and woke in the morning with his eyelids sealed down with mucous matter. In a case like this it is best to use spectacles of ordinary blue or smoked glass, and to wash the eyes morning and evening with rose water, or even three or four times a day. But it is far better to try to prevent the disease by having recourse to proper precautionary measures. A simple washing of the eyes with fresh water whenever they have been exercised for a long time or very attentively, and adopting the precautions of not reading or performing any work during the evening, as likewise not smoking, and taking but little wine and coffee, and no spirits, are the best means to take under such circumstances. Measures such as these will have the effect of preserving the first and most important of our faculties—our eyesight.

Another injury may arise from the curved position assumed by the operator in the process of retouching. It may happen to the retoucher, as it does to the copyist, the writer, the clerk, and all those who work in this attitude, that they suffer from a pain between the shoulders, from cramp in the stomach, and injury, more or less great, to the digestion. But from these maladies there is little to fear by those who enjoy good health, who take moderate exercise out of working hours, and, living a steady life, have good food, and abstain from an excess of alcoholic drinks.

To resume: we may here repeat what we have already said, that there is nothing in the photographer's calling really injurious to health or to life. The danger does not lie here; it is rather in the ethereal atmosphere which those who follow the profession breathe continually, and to ameliorate the effects of which we have recommended some precautionary measures to be taken. Danger lurks likewise in the daily manipulation of certain irritant and tonic chemicals, a subject with which we shall now proceed to occupy ourselves.

*On the Action of Chemical Substances in General.*—All chemical products exercise disturbing effects upon the human system, and these actions, if wisely regulated, become in medicine of very great assistance; but if such compounds are employed ignorantly, or in too large quantities, they are greatly prejudicial to health, and bring about what we term a poisoning action.

As a matter of course, all chemical compounds do not possess the same amount of energy in their action, and there are some which are only injurious when taken in wholesale doses, so that it may be asserted no fear need be entertained from their use. But there are others, again, which act upon our systems with extreme violence, either by corroding the tissues with which they come into contact, or by penetrating deeply into the body by rapid absorption, and directly influencing the circulating organs, or, what is more important still, our delicate nervous system. Of these truly poisonous agents there are several in use by photographers, and others are daily coming into play. Among them may be enumerated: cyanide of potassium, nitrate of silver, bichromate of potash, bichloride of mercury, &c. We propose to say a few words on the subject of each of these preparations.

*Cyanide of Potassium.*—Cyanide of potassium is employed in the form of a solution for fixing images upon collodion. Photographers, also, are in the habit of using the noxious drug for removing from their hands nitrate of silver stains of all kinds. This latter is a most dangerous and reprehensible practice, for the salt is, without doubt, one of the most violent poisons we have, even in small quantities, and it is, moreover, a substance easy of absorption, and one

so sudden and rapid in its action that it is difficult for medical aid to step in in time to stop its baneful effects. It would be desirable, indeed, that such a compound should disappear altogether from the photographer's laboratory, and other chemicals are not wanting to replace it.

The energy of this poison is such that it is only necessary for a cut to exist, or an abrasion of the skin, in order to bring about absorption, when a solution comes in contact with the hands, and in this case, results of a most serious character at once ensue.

Photographic operators who so often work with the dangerous substance, and in a manner, too, both thoughtless and imprudent, often have their fingers chapped and cracked in winter time by the frost and damp, and the existence of such wounds in the hands during the manipulation of cyanides opens the door to fatal accidents. And accidents from this poison are by no means rare. They do not, it is true, always bring about death, and the greatest number are fortunately of a mild character, but there are cases of paralysis and other nervous diseases which are the effects of such accidents, and which should cause operators to reflect, and put them on their guard. Unfortunately they do not heed the lessons thus given, and the cases of accidental death that have come about by the imprudent employment of cyanide of potassium do not, of themselves, suffice to correct the habitual carelessness of photographers in the matter.

Let us add, finally, that there are to be found among photographers, as among other classes, unfortunates who are so unconscious of duty—so oblivious of the dignity of human nature—that they quit voluntarily their place in the battle of existence, desert life, and commit the crime we call suicide. These have looked around them, among the materials in use in their profession, to see which of them all would the swiftest, most surely, and least painfully aid them to attain their sad and miserable end; and it is to cyanide of potassium that they most frequently have recourse.

It is because photographers are liable to see and hear of cases of poisoning by cyanide, absorbed either voluntarily or involuntarily, that we deem it right to indicate the symptoms of such poisoning, and the means for relieving it.

The first effects of cutaneous or digestive absorption of cyanide of potassium, even when taken in minute doses, are great pain in the region of the heart, headache, giddiness, deafness in the ears, sleepiness, and a painful respiration, which is sometimes slow and sometimes fast, but which is always interrupted by profound sighs. If the dose is larger, and especially if the poison has penetrated into the stomach, the patient experiences a bitter taste in the mouth, a burning in the throat and stomach, a desire to vomit, a great increase in the secretion of the saliva, and diarrhoea. At the same time the pulse is feeble, and even insensible; the eyesight is troubled, the pupils are dilated, and the eyes appear enlarged. A cold perspiration suffuses the body.

In very grave cases a general prostration is manifested, interrupted from time to time by convulsions. Every movement ceases, and death ensues in a syncope. All these phenomena come to pass with terrible rapidity, allowing one barely time to observe them, much more to interrupt them.

After a cure has been effected, whether by reason of the insufficiency of the dose, or, artificially, by reason of prompt and energetic remedies, it is never altogether complete. Nervous affections come on, and remain for a considerable period; frequent giddiness in the head is experienced; one is troubled with pain in breathing, and sometimes a partial paralysis of the muscles ensues.

Whenever an accident happens from cyanide, from imprudence—say, for instance, in the case of an operator placing his chapped and broken hands into cyanide solution—the first thing to be done, in the case of a symptom of giddiness or fainting being felt, is to wash the wound in

chlorine water—that is, water saturated with chlorine at the ordinary temperature. The patient should also immediately take two or three grammes of the same in a glass of water without waiting to put a piece of sugar into it. He is at once put to bed, and covered with warm blankets, hot water bottles being placed at his feet and along the whole length of his body: or, if a bed is not handy, he is placed on the first couch or sofa, and wrapped warmly in coverlids or garments. The windows are opened everywhere, for while it is necessary that the patient should be warm, it is requisite also that he should have plenty of air, and that it be very pure.

In the meanwhile a messenger has been despatched to the nearest chemist's for a few grammes of laudanum. Tea or coffee is prepared, and sugar and rum or brandy are obtained, and the patient receives a cup of tea or coffee with ten drops of laudanum and one or two spoonfuls of any alcoholic liquid, such as rum or brandy; *kirschwasser*, however, must on no account be given. A cup of tea or coffee with the same quantity of laudanum (ten drops) may be given three or four times running at an interval of a quarter or half an hour.

If the accident has been marked at the commencement by very serious symptoms, and if the cyanide has been taken internally, then, without hesitation, five grammes of chlorine water should be given in a glass of water. The patient is put to bed, with plenty of warmth and air, as just described, and he should be allowed to breathe frequently over a vessel of chlorine water placed under his nose. Every quarter of an hour a cup of tea should be taken, with cordial of some kind, and ten drops of laudanum (not more, however, than four or five cups being given), and every five minutes a teaspoonful of the under-mentioned potion is administered:—

Chlorine water	...	...	5 grammes
Chloro-hydrate of ammonia	...	2	"
Sugar water	...	250	"

As soon as the patient seems to be growing better, the laudanum in the tea is suppressed, and the potion is taken only every quarter of an hour, and afterwards every half hour. This treatment does not, however, remove the responsibility of sending for a medical man, who, on his arrival, will continue or modify the regime according to discretion.

One of the antidotes against cyanide of potassium is said to be a mixture of hydrate of protoxide and peroxide of iron. It is, no doubt, a very good specific, but, besides the fact that it is not usually at hand, it is, we think, scarcely so efficacious, nor so easy to absorb into the system, as chlorine.

Ammonia has also been mentioned with favour, and with some right too. If chlorine is not at hand, it would be well to get the patient to breathe ammonia vapour, and to administer to him fifteen or twenty drops of liquid ammonia in a glass of water.

The application of cold water to the vertebral column seems to have succeeded in some cases of poisoning by prussic acid and the cyanides. If we do not counsel such a course, it is because it must be conducted by a skilful hand, and only in cases where the medical man thinks such a course desirable. Applied without care, a chilling action might be produced, which favours the noxious action of the poison.

The means we have recommended—chlorine, laudanum, tea, and coffee, with rum—are not only the best and most efficacious; they are also those whose employment we consider the most simple and most convenient.

But it must always be borne in mind that cyanide of potassium always acts with extreme rapidity, and that the delay of a minute, or even a second, in the application of the remedy may be altogether irrecoverable. For this reason we would suggest that in all laboratories and studios there should always be kept a supply of chlorine water and laudanum ready in case of accident.

It is only, we repeat, by having recourse to prompt and

immediate action that there is any chance of combating against poisoning by cyanide of potassium, until that dangerous compound is banished altogether from the photographer's studio. But it is not only on account of accidents that we should be glad to see cyanide of potassium disappear from the chemical laboratory, for accidents happen from ignorance and imprudence, and, consequently, may be avoided; it is by reason of its dangerous influence at all times, for the vapours of hydrocyanic acid and iodide of cyanogen which are disengaged in photographic manipulations are also poisonous and injurious to breathe. Every photographer knows this, and all are cognisant of the headaches and giddiness they give rise to. Ammonia may be beneficially used to give relief in these cases.

(To be continued.)

## ON THE CONTRACTION OF THE COLLODION FILM.

BY DR. H. VOGEL.\*

The results of Paschen and Rutherford upon the construction of the collodion film have already appeared in these pages. They differed very much from one another. Paschen found a contraction in the film of one six-hundredth, while Rutherford stated that it amounted to a twenty-four thousandth only. These very important differences can only be explained by the assumption that the contraction in different collodions varies very much, and this assumption is supported by practical experience.

To investigate the matter thoroughly, I tried several collodions of Berlin, St. Petersburg, and Paris manufacture, and obtained at once the most varied results. The contraction of the film often betrayed itself during the washing of the plate; the collodion left the margin of the plate, and on drying the edge of the glass was at some distance from the border of the film. In this way, however, I only remarked the worst forms of contraction. To observe the less remarkable phenomena I had recourse to the following process.

Upon a glass one hundred and ten centimetres in length were scratched, by the aid of a diamond, a net-work of lines crossing each other at right angles, the strokes being provided with numbers. Under this network the films of collodion to be tested were exposed to light, strips of writing-paper being placed between the surfaces to prevent the collodion coming into actual contact with the scratched glass. The paper between was so thin that the lines printed perfectly sharp; but it was necessary that, before exposure, the plates should be allowed to drain for four or five minutes, so that all the liquid might be removed.

The exposure of the plates was managed by the opening and shutting a window in the dark room, whilst the plate was held at a distance of ten feet from it in an upright position parallel to the window.

The exposed plate was developed partly with sulphate of iron solution, and partly with pyrogallic acid; in the case of dry plates, alkaline development was employed; and for fixing, both soda and cyanide of potassium. Indeed, everything was essayed as in the case of actual practice. To test the amount of contraction, the plates, when dry, were placed upon the network, and examined by transmitted light. It was easy to compare the lines printed upon the film with those scratched upon the glass.

In this way the two surfaces were put under a microscope magnifying five-and-twenty diameters. With this power the division between the lines, which amounted to one-fiftieth of a millimetre, was easily recognisable. The total contraction could, therefore, very easily be estimated. If, for instance, at one end, the two lines were coincident, while at the other end, at a distance of ninety millimetres, one overlapped the other by a fiftieth of a millimetre, then the contraction would be equal to  $\frac{90}{50} = 1.8$ .

\* Photographische Mittheilungen.

In my first experiments the results furnished by various thick and tough collodions were very different, and for this reason I placed these on one side. The most suitable collodions which, according to preliminary experiments, contracted the least, were Mann's collodion from St. Petersburg, and Schering's collodion. With both these compounds I made more searching investigations. A material was prepared according to the following formula:—

Pyroxiline ... ..	2 parts
Alcohol ... ..	50 "
Ether ... ..	50 "

And to this compound was added, to the extent of one-third its volume, of the following,—

Bride of cadmium ... ..	5 parts
Bromide of cadmium ... ..	1 part
Alcohol ... ..	90 parts.

I found that the contraction of the film depended very much upon the amount of adhesion existing between the collodion and the glass. As soon as the film in washing has become loosened from the margin of the glass, or as soon as water gets between the film and the glass, or the former is ruptured in any way, then contraction of the film at once sets in.

It is therefore indispensably necessary, when contraction is desired to be avoided, to prevent any separation of the film from the glass when the plate is in a moist condition. This can only be brought about by giving the plate a preliminary coating of albumen or india-rubber, or the latter may be applied to the margin of the plate. The same holds good with dry plates. It is only in the collodio-albumen process where such a preliminary coating is unnecessary, for here albumen penetrates through the collodion, and cements this down.

I employed, in the first place, india-rubber applied to the margin of my plates, which were coated with Schering's collodion. The following plates were prepared:—

1. Collodion film on polished glass surface, margin of india-rubber, fixed with soda, and varnished.
2. Collodion film on polished glass surface, margin of india-rubber, fixed with soda, and not varnished.
3. Collodion film on an albumen substratum, margin of india-rubber, fixed with soda, and not varnished.
4. Collodion film on polished glass surface, margin of india-rubber, unfixed, and not varnished.
5. Collodion film on polished glass surface, margin of india-rubber, fixed with cyanide, and not varnished.

Of all the plates here enumerated, only No. 1 showed signs of contraction. This seemed irregular, and in some parts there was, indeed, a slight expansion of the film; all the other plates agreed very well with the original. Afterwards, Mann's collodion was used in the preparation of a similar number of plates, and in this case, too, No. 1 (the varnished plate) showed an irregularity as before. No. 2 showed a very important contraction on that side where the collodion was thickest; the contraction amounted to  $\frac{1}{250}$ . On the thinner side the contraction was not noticeable. The albumenized plate behaved in like manner; on the side where the collodion was thinner no contraction had taken place, on the other it amounted to  $\frac{1}{450}$ . Plates 4 and 5 showed a slight contraction on the thicker side, but were otherwise perfect. Thus it may be inferred that the Schering collodion is the more stable one.

This collodion is somewhat more limpid than that of Mann, and from this fact, as also the circumstance that the contraction was remarked upon the thicker, and not upon the thinner, parts of the films, led one to the belief that the consistence of the collodion exercised great influence in the matter. To prove this, Mann's collodion was diluted with one-third its volume of alcohol and ether, and a series of plates again prepared with the same. I found that the collodion attached itself more firmly to the glass under these circumstances, a fact which spoke much in its favour.

The contraction in the case of the dilute collodion was notably less than in the thicker material. A quite unimportant degree of contraction was exhibited upon the albumen plate, on the thick side of it, which was certainly less than 1-6000th. The varnished plate, and that fixed with cyanide, were good.

From this it follows that contraction is less liable to ensue in a thin than in a thick collodion.

The collodion collodion, I found, was subject to contraction when containing more than one and a-half per cent. of pyroxiline; thick residues from the collodion bottle gave films which contracted on the thick side of the plate to the amount of 1-4500th.

Under these circumstances I am not surprised that the Fothergill plates tested by Dr. Weinesk and Dr. H. C. Vogel betrayed no trace of contraction, for these are prepared with very thin collodion, containing but 0.9 per cent. of pyroxiline.

In conclusion, I tried, instead of a margin of india-rubber, a preliminary coating of the same material all over the plate. One part of india-rubber was dissolved in one hundred parts of chloroform, and this was subsequently diluted with 900 parts light benzole. This dilute and perfectly clear liquid was applied to the glass plate; the film dried very rapidly, and yielded, with the wet process, images of great clearness, and quite free from any visible contraction. The india-rubber solution is easily manipulated, and may be recommended in place of the so easily decomposed albumen solution.

Next, some dry plates were essayed of bromide of silver, the films being prepared with Mann's collodion. Their preparation was conducted in the simplest manner by coating a polished plate with a margin of india-rubber solution, with bromide of cadmium collodion, sensitizing the same, and then washing it. One of these plates was developed with alkaline solution, the other with an acid one of sulphate of iron. In the latter case the film became loosened during its development, and separated from the edge of the plate. After drying, a great degree of contraction was apparent, to the extent, namely, of 1-300th.

It is known that in the wet process a film will become much contracted through continued application of an acid developer, and the same thing occurs in a most marked degree when dry plates are much forced with an acid developer. The alkaline developed films held fast to the plates during development, and showed no signs of contraction. It was different, however, with Wortley bromine plates, which contain gum, for these showed, on treatment with an alkaline solution, both a lifting and contraction of the film.

It may be taken for granted, therefore, that dry plates which do not contain gum have perfectly stable films, and for this reason preservatives of this kind should be avoided when great stress is laid upon the rigidity of the collodion surface.

Bromide plates require very careful handling, and their perfect production under the vicissitudes of travelling would be very questionable. For this reason I experimented with another dry method, that of morphine. This is a very simple process, for no other chemicals are required beyond the morphine itself. The plate is prepared in the ordinary way, and then covered with a very dilute morphine solution of 1-1750 strength. This extreme dilution of the solution prevents the risk of any danger from the subsequent action of the coating.

The plates themselves are very sensitive—when freshly prepared, one-third as sensitive as wet plates—and therefore to be preferred to the otherwise very excellent Fothergill films, which require ten or twenty times the exposure of wet plates.

The limited keeping qualities of morphine plates should be no hindrance to their employment for astronomical purposes, as it is very easy to prepare a hundred of them one or two days before they are required.

There is, however, another circumstance of importance, which I ought to mention in connection with morphine plates. I have found that when exposed to the spectrum they are much more sensitive to the green and yellow rays than wet plates or dry films of other kinds. Now, Dr. H. C. Vogel has proved that the circumference of the sun is much less chemically active than the middle, and for this reason the former appears usually somewhat under-exposed, and in short exposures to such a degree that one can scarcely make out the outline of the body. According to photo-spectroscopic results, it may be anticipated that morphine plates will give a much better defined outline, and for this reason will allow of finer measurements being taken. Up to the present moment I have been enabled only to make a couple of experiments with morphine plates in murky weather; but, nevertheless, the limbs of the sun came out most satisfactorily upon my plates.

### Correspondence.

#### STRONG DEVELOPER AND THE ALBUMEN AND BEER PROCESS.

SIR,—I notice Capt. Abney's letter on his albumen and beer process.

Clearly, working with the albumen so as to allow of my strong developer being used is a most important improvement, and one which will much conduce to the success of Capt. Abney's process.

If the albumen is left on, I think he will find that by first applying the pyrogallie acid alone, and then adding the ammonia, the strong development becomes manageable; at least, I do not myself find difficulty in working thus when experimenting.

II. STUART WORTLEY.

#### BLISTERS IN ALBUMENIZED PAPER.

DEAR SIR,—Having received nearly the whole of my photographic knowledge from the PHOTOGRAPHIC NEWS, I beg to offer a brief item for the benefit of others. I observe in the NEWS for June 12th that the Edinburgh Photographic Society discuss from their question box, the enquiry, "What is most likely the cause of, and best remedy for, the blistering of albumenized prints?" Now, I have been troubled but very little with blisters, until the beginning of last winter, when, on taking a batch of pictures out of the washing pan, I found them covered with blisters so thick that they would not even come to a smooth surface with very heavy rolling. It completely puzzled me; and thinking the matter over, I concluded it was owing to the cold weather. With my next batch of prints, therefore, I made the hyposulphite of soda warm, or even hot. It is important not to put the prints into cold water after this, but into warm, nearly the same heat as the soda; let that get quite cold before you add any cold water: if you add cold water you force blisters immediately. I worked the plan all the winter, and quite got rid of blisters. I occasionally go back to the cold hypo.: it blisters immediately. Always make the hyposulphite warm; after mixing, standing in the sun will do in the summer. If the hyposulphite has been made a few days, and gets the same degree of heat as the printing room, it will have the same effect. The paper I used was Thomas's Rive.—Yours, &c.,  
RICHARD HUCK.

### Talk in the Studio.

COAGULATION OF ALBUMEN.—A recent communication to the Academy of Sciences at Paris states that the tendency in albumen and serum to coagulate depends on the presence of carbonic acid in the substances, and that if it be completely removed neither will coagulate, even at the temperature of boiling water; whilst the restoration of the carbonic acid revives the capacity of coagulation.

THE ANTHONY PRIZES.—We recently announced decisions in regard to a series of prizes for photographs offered by Messrs. Anthony, of New York. We have just been favoured by Mr. Badeau, a member of the firm, with some examples of the prize prints. Two of these are half-plate portraits of children by Gutekunst, of Philadelphia, both very fine; but one, especially, is exceedingly beautiful—a charming portrait of a charmingly pretty little girl—"Little Adele." We do not

exaggerate when we say that as a picture it might have been regarded as a *chef d'œuvre* by Sir Joshua. A whole-plate portrait of a lady, by Barhydt, of Rochester (U.S.), is a piece of very fine work, doing full justice to a model of unusually fine features and winning expression.

### To Correspondents.

DARTMOOR.—As we mentioned in our article referring to the matter, the metallic precipitating bars were announced by a dealer in photographic materials in America, not in this country. You can easily obtain something which will answer the same purpose of any worker in zinc.

SPOTTING.—You will find various articles devoted to spotting and retouching in back volumes of the NEWS and back YEAR-BOOKS. We cannot devote much space to detailed instruction for carrying out any branch of work in this column, but as you are a constant reader of the NEWS you will have no difficulty, we presume, in referring to our volume for 1871, where you will find many articles on the subject. The preparation for spotting out negatives which we noticed in our last will help you much. You simply require the preparation in question, a fine pointed and not too long haired sable pencil, and a steady hand. The great point is to avoid, in filling up pinholes, &c., spreading the colour you apply so as to make a large, white spot, requiring much retouching in the print. In retouching the print, mix water colours to match the tone of the photograph; warm sepia, Indian ink, and purple madder will give a good tint for most photographs, and sometimes a little crimson lake may be added. You may mix with the tints a little fresh gum, or a little albumen. Work with as dry a brush as you can conveniently.

C. A. B.—There may be many causes for your negatives being thin, and intensifying imperfectly. One of the most common causes is the use of a thin, new collodion. The addition of a little collodion which is older and has more body would help you in such case. It may be that your silver bath is getting weak. It sometimes happens that in pouring on the developer the free silver on the plate is driven off and spilt, and a thin negative generally results. After developing, wash well, then treat the plate with a solution consisting of one grain of iodine, two grains of iodide of potassium, and an ounce of water; wash, and apply the pyro and silver, or iron and silver developer. You will rarely, in such case, have much difficulty in securing intensity. 2. The brass work to which you refer is probably lacquered, and has had the lacquer removed by wear. Wash with soap and water, and relacquer with a spirit varnish in which a little dragon's blood or gamboge is dissolved.

SILVERTIDE.—Have you any reason to believe that the trough contains any silver? It will not necessarily do so. If there be any, the simple plan will be to scrape it away from the surface, recovering the silver by adding hydrochloric acid.

TRY-AGAIN.—The process of applying the plumbago in powder is a very slow one, and requires patience; gently and steadily applying a little at a time with a soft touch of the brush, which should be applied with a circular motion. By continued application, you may impart a thick deposit, producing a dense negative. You can either transfer to leather collodion, of which you may have a film on both sides of the gelatine negative, or you may transfer to glass.

B. L. D.—For landscape work pure and simple your single lens will answer every purpose, and for the interior we should use a portrait lens, stopped down no more than is absolutely necessary to secure definition. Use wet collodion for the latter if you can, but avoid the repellent collodion, which gives matt stains for a purpose in which a somewhat extended exposure is unavoidable. We should use an ordinary iron developer.

G. F. T.—The addition of alcohol to the printing bath at the rate of three ounces to every pint of water will aid materially in checking the tendency to discolouration in the silver bath. Making the silver bath of hard water instead of distilled water has been found a preventive of discolouration.

E. M.—The collodion is in fault. The reticulation is due to the use of too weak solvents in making the collodion. But for this, your attempt to manufacture collodion is apparently successful. It is probable that you have used ordinary rectified spirits of wine, which is not sufficiently free from water to be used in equal parts with ether in making collodion. Ordinary methylated spirit is generally about 63 over proof, and spirits of wine about 50 over proof.

COMMON SENSE.—You misunderstand the matter entirely. It has no reference to England whatever, but to the far West of America, and is an example of the idea of *fun* prevailing there.

D. F.—The example of double printing with two distinct tones is, we have no doubt, the result of printing one portion in the sun and the other portion in the shade. There is generally a tendency in full sunshine printing to give warmer and more foxy tones than in diffused light. We some years ago fully described a series of experiments we made in this direction.

Several Correspondents in our next.

## The Photographic News, July 3, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PURE PYROXILIN—THE PARIS PHOTOGRAPHIC EXHIBITION— UNION IS STRENGTH.

*Pure Pyroxilin.*—The employment of celloidin gun-cotton—or, in other words, pyroxilin which has been dissolved in ether and alcohol, and precipitated by the addition of water—has found little favour in this country, although some of the principal studios in Berlin and Vienna employ it. There can be no doubt that a product such as this, provided it always gave a stable film upon the glass, has very much to recommend it, for it may be considered entirely free from matter likely to act injuriously upon the silver bath or upon the image. Chemists will tell you that this is about the only way in which chemically pure, soluble pyroxilin can be produced, for when the flocculent masses of gun-cotton are precipitated by the addition of water to collodion, the gummy matter, mineral impurities, &c., which may chance to exist in the solution, are left behind. In pursuing a chemical investigation, a chemist would, in all probability, pursue this course to obtain the pyroxilin perfectly pure. The drawback to this plan of purifying is, of course, the increase of cost that would be naturally involved, for although the recovery of the alcohol and ether is possible, still it is always a costly operation. But there is a plan we might point out by which the purified product could be obtained at comparatively little cost, by utilizing, namely, what is comparatively a waste product now-a-days. Large quantities of gun-cotton are about to be made in this country for military purposes, and its manufacture is also shortly to commence on a large scale in Prussia. Our war authorities, however, only want the most explosive form of pyroxilin, which is not soluble, and one of the tests to which it is subjected, before the product is accepted by Government, is its examination for soluble cotton; for if it should contain as much as fifteen per cent. of soluble pyroxilin, a supply would be rejected, and thrown back upon the contractor's hands. Now it would seem to us that although the quantities tested may be from a military point of view, very small indeed, it would be quite the reverse from that of a photographer: and if in these waste solutions the pyroxilin were recovered as a precipitate, the same would furnish a most excellent material for collodion. When, therefore, the manufacture becomes more thoroughly developed in this country and in Germany, there ought to be no difficulty in supplying celloidin collodion at as reasonable a rate as the ordinary material, and in this way photographers would have one difficulty less to contend with. Indeed, it is not at all unlikely that the manufacture of gun-cotton for military purposes may be carried on as extensively as that of gunpowder, and in this case the photographer would reap a great advantage. The usual test for highly explosive pyroxilin is to wash fifty grains of it in about eight ounces of alcohol and ether, and this amount may contain, after the operation, from twelve to fourteen grains of gun-cotton. So dilute a solution need not be precipitated, but might be reduced to at least half its bulk before treatment. Besides the removal of foreign matter, this purification of the gun-cotton does away with every trace of acid.

*The Paris Photographic Exhibition.*—Honours have been falling thick upon the exhibitors at the Paris Photographic Exhibition this year, and we are told that nearly every British exhibitor has received either a medal or honourable mention. The names of the English medallists are: Mr. William Bedford (whose works are specially commended), Mr. William England, Mr. D. Hedges, Mr. Johnson, and Mr. Woodbury. Honourable mention has been awarded to Mr. Brownrigg, of Dublin, and Mr. Diston, of Leven. Altogether, however, there are only eighty-six exhibitors,

so the contingent from this country cannot be very large. Of these eighty-six, more than half—forty-five—have been awarded medals, while the other forty divide a score of honourable mentions among them, leaving but twenty out in the cold. The collection of pictures is said to be a very good one, as might well be the case with all these prizes. As the exhibition will remain open during the summer, and not close before September or October, some of our readers may get the chance of a look round before the end of the season. The last exhibition in Paris was held four years ago.

*Union is Strength.*—The premises of the Scientific Club have now been formally opened in Savile Row, in the vicinity of the popular Savile Club, which is, by the way, more scientific than anything else, for although artists and authors are to be found among its members, the great bulk are professors attached to the London colleges, medical men, &c. We are glad the Scientific Club is a success, for now that nearly five hundred members have joined, it may be considered so, because, by the combination of scientific men in this way, it will be more easy to make a forward movement at any time, and get themselves properly represented. Every day our learned bodies are acquiring more weight and influence, and the Government of to-day is bound to consider their interests. The mere fact that a man of high scientific attainment—Dr. Lyon Playfair—was among the Ministers of the Cabinet during the reign of the late Government, alone proves how great was the desire to have advice such as he could afford; and the rumour respecting the appointment of a Minister for Education is a step in the same direction. And if such advances are made without any combination among scientific men—for our different learned societies are, unfortunately, quite independent of one another—how much more could be effected by pressure exerted from a united body representing all branches of science! It is for this reason, especially, that we are glad to hear of the establishment of the Scientific Club, for it is a step in the right direction to bring scientific men together, to aid one another in progressing onward.

### ON COPYING AND ENLARGING.

BY R. J. CHUTE.

ONE of the first requirements for enlargements is a long box or camera, made in two or three sections that slide into each other, so that any desired distance may be readily had. For enlarging, a quarter or half size portrait tube, with central stops, is suitable. The front of the camera should be so constructed that tubes of two or three different sizes may be put on or taken off without delay. If a Daguerreotype be tarnished, it should be cleaned. This is done by holding the plate by the lower left hand corner in a pair of pliers, and after washing under a gentle stream of clean water, flow with a weak solution of freshly-prepared cyanide, or a solution that has not been used for any other purpose; let it be on the plate a few moments, or till the tarnish is removed, then wash thoroughly, and warm over a gas flame or spirit lamp till with one good breath the surface can be blown dry without any stop. The full sunlight is best, and, for a Daguerreotype, should be reflected from a mirror about on a level with the camera. Should the Daguerreotype be rubbed or scratched, it may be better to copy in diffused light, placing it in such light and position as will show the marks the least. Ferrotypes and tintypes, if at all old, will need revarnishing, as it removes all little scratches in the varnish, gives brilliancy to the picture, and saves a great deal of after labour in the copy. Further than this, a ferrotype may be preceded with the same as a Daguerreotype, with the exception that the former will require about fifty per cent. more exposure. In copying either of the styles just referred to a copy may be made in one-third the time or less, and be more bril-

liant and perfect, by using a condenser, like a burning glass, to concentrate the rays of sunlight on the picture being copied. It is not necessary to have a lens especially for the purpose, as the front lens of any large portrait combination answers very well.

In the absence of a reliable enlarging process for negatives on hand, make a good print, and, taking a clean plate of glass, plunge the picture and glass into a dish of water, and then bring them in contact with each other; then remove, and, if free from air-bubbles, place over the back of the print a piece of wetted blotting-paper. In this condition the picture may be copied in direct sunlight, or in the diffusion of a ground-glass skylight; in either case use the mirror to reflect the light as nearly as possible in the opposite direction from that in which the direct light falls. In this way a card-sized head may be enlarged to life-size with very little roughness from the texture of the paper. Photographs of any size, architectural drawings, manuscripts, maps, &c., may be copied successfully in the same way. A great advantage is gained in using a reflected light opposite the direct light.

For architectural drawings, models, &c., where correctness of line and form are required, a good copying or view lens is necessary.

In copying of any kind, a more perfect immobility is necessary than in making sittings; all jar or vibration should, therefore, be avoided. To succeed well in copying, it is of the first importance that all the arrangements should be made with care, leaving nothing to hap-hazard or luck. The copy is more than half made when, in a good light, all the preparations are made with a purpose to secure the best possible result. For copies requiring black and white, a thick collodion should be used, with a little less bromine.—*Mosaics.*

## A PHOTOGRAPHIC ALBUM.

BY E. LEGOUVE.\*

PHOTOGRAPHIC collections are now in vogue. They are found on almost every centre-table, and each one is both the portrait of those who are placed therein, and of the one who composed it. One of these albums which recently fell under my observation struck me by its peculiar character, and suggested to me the idea of addressing you for a moment concerning that marvellous discovery which pertains to art, science, history, and the family; which is intended as well for the most obscure beings as for the most illustrious; and which satisfies one of the most ardent desires of our mind, and also one of the most profound longings of our heart.

Madame de Staël died conversing. In vain, for several days, her relatives, seeing that the fatal end was near, wished to prevent visitors from approaching her bed of agony. "Let them enter! let them enter!" cried she, in a feverish voice; "I am athirst for the human face." This deep and almost terrible phrase expresses one of the most ardent passions of our day: we are all athirst for the human face. Stop at the printsellers: see what a crowd is found before the showcases containing photographic exhibitions, and observe what eager investigation. Let the picture exposed be that of a criminal, or of a man of genius, of an actress, or of a general, of a sovereign, or of a poet, there is the same eagerness to examine the brow, the eyes, the physiognomy. Is this pure curiosity, simple love of amusement, frivolous idleness? No! There is something else besides the desire of looking, in that insatiable ardor of looks; there is a deep and characteristic longing of modern intelligence. We are all athirst for the human face, because we are athirst for the human soul.

\* Our American contemporary, the *Photographic Times*, translates this charming article by Mons. Legouvé, of the French Academy, considering that there is too much suggestive excellence in it to be lost to photographers.

Our age, truly, is not one of imagination and poetry: reality alone interests it deeply. In science the time of systems is passed, the reign of direct experiments is come. In history we require absolute truth; we wish the historian to know and tell us about great men as much as their valets could. At the theatre the surest road to success is to relate at night to the public what it has seen and heard in the morning; it matters little that what it has seen may have been ugly, and what it has heard may have been painful; the public is satisfied if it be a reality, and the bitter pleasure of proving the existence of a vice or a foible is a consolation for seeing, and even for having it. To this may be attributed the immense success of Balzac. No writer has uncovered more human ugliness; none has probed the soul so deeply, often to bring forth only hideous monsters; and none has inspired so much sympathy and admiration. Is it not strange? The more he drives us to despair, the more we are drawn to him! Why? Because the more he afflicts us the more true we believe him to be; and because he thus satisfies the ruling taste of our mind, and our most cherished pretension to show the bottom of things, and not to be dupes.

This double frame of mind explains our passion for the photographs of celebrated persons. We are not satisfied with knowing what they have done, we want to know what they are.

Now, who or what will give us this information? Is it their reputation? Fame has a hundred mouths only to lie in a hundred different ways. Is it their works as poets or painters? Artists show in their works only their best side; sometimes, even, they put the opposite of what they are. I have known a painter, celebrated by the fury of his battle pieces, who was prudence personified; he expended so much courage on his pictures that none remained for his private life. Finally, shall we judge men of action by their actions? Nothing is less certain. We are almost always worth a great deal more, or a great deal less, than what we do. A great many culprits are less criminal than their crimes; and there are very few heroes who are as heroic as their actions. Were we to penetrate to the inmost recesses of that heart which gave birth to any culpable or praiseworthy action, we should be amazed at the difference which exists between the deed and the doer, between the tree and its fruits. Surrounding circumstances, the moment, the secret motives, the inducements, play so great a part in our actions, that we ourselves can only be counted for one-half in their accomplishment; all of us have events as anonymous collaborators.

Now, in the acts of celebrated men, what is the exact part that belongs to them? What relation, what proportion, exists between what they have done and what they are? This is what we are so desirous of ascertaining, and what we seek to find in their portraits. We summon before us the human face as a last witness, a witness who does not tell all, but who tells what no other can; a witness for the prosecution and defence, who aggravates, attenuates, completes, or corrects, the other testimony; a witness furnished by the Creator Himself, and who, if consulted with circumspection, rarely lies and seldom deceives. As a general rule, men have the face they deserve to have. Now, that is what, henceforth, photography will give us; and that is what has been attempted, and partly realized, for the present time, in the album of which I have spoken.

He who has formed it, nevertheless, is neither a *savant*, nor an historian, nor a moralist; and his collection resembles in no manner a complete and methodical gallery of contemporaneous celebrities. Being a man of the world, a man of wit, a critical amateur of what is piquant in the actualities of life, he has endeavoured to express, by this collection of portraits, the face of the fleeting world in which we live.

To that end he has gathered from the Parisian *Flora*

(for it is essentially a Parisian album) a hundred—What? Celebrities? Oh, no! That word is too big for the purpose. Some of the persons who figure there will perhaps soon be simply distinguished characters; in a few months they may be merely notabilities; a little later notoriety; and will end, I fear, by becoming unknown. No matter, it will only be the more curious, and the contrast more striking. In it a statesman faces a prima donna; a sovereign forms the companion picture to a tenor; a cabinet minister smiles at the one who is to succeed him; opposite to the noble front of an immortal poet shines the ephemeral beauty of a woman of fashion, and the evanescence of her reign of a day but adds to the charm of the collection; as we all know, falling stars are not the least attractive ones in the azure vault.

In running over these portraits a reflection came to my mind, and I said to myself: These persons are better likenesses of themselves than they imagine, for, without being aware of it, they have worked to make their own portraits—they have been at the same time models and painters. More than one, I am sure, on seating himself in the photographic chair, has taken his preferred pose, his favourite expression, that which depicts not what he is, but what he believes himself to be. Here is one, for example, who smiles with a cunning air; evidently he thinks himself witty. This other one, with his eyes raised to heaven and his dishevelled hair, belongs to the class of inspired poets! I would be much surprised if this person who looks at you full in the face with piercing eyes, as if he wished to transfix you, were not murmuring to himself, "What an eagle eye is mine!—nothing escapes me." Finally, as to this young legislator, who carries so proudly his seven hundred and fiftieth part of sovereignty, it is evident that when he once mounts the rostrum it is not easy to get him down; I am certain that, vain of his twenty-five years, he snubs his senior colleagues.

In a word, photography gives us at the same time the portrait of our persons and of our pretensions. The result is that I look upon it as being very healthy to have one's photograph taken from time to time. A good photograph is equivalent to an examination into one's conscience. Photography places under the eye more than one secret foible that you were loath to acknowledge, and brutally throws your age at your head. That man of fifty, of sixty, if you choose, if he be sincere, does not murmur to himself, when looking at his photograph: "Gracious heaven! how old I am! How! All these wrinkles are mine! What! This sad, worn, furrowed face belongs to the gentleman whom I shave every day! It is not to be believed!" One is stupefied, and this stupefaction is often increased in a very disagreeable manner when showing this photograph to some friends. One hears them exclaim: "Oh, how perfect! It is you! Now you have a portrait that looks just like you!" Thank you.

Ah! although we may believe ourselves to be sensible and philosophical, and despite our endeavours to pluck from our hearts all its illusions of vanity, as a good gardener tears up the evil weeds in his garden, we always have inside of us a portrait of ourselves much finer than the reality. Within us there is no register of our position, there is no baptismal record; the inner man is always young. Do we come across an interesting book, and feel the same enthusiasm that we felt at twenty-five; does a touching story bring tears to our eyes; does a beautiful face charm us as it did at twenty-five? Then we believe that we are only twenty-five. I am sure that when the old men of Troy, standing up before Helen, cried out, "How beautiful she is!" they forgot their age; they believed themselves to be young; they were so in reality inwardly. Yes, inwardly; but what of the outside?

Oh! be advised by me, all you, my contemporaries, my elders, and even my juniors; have your photographs taken. If you feel within you any awakening of vanity, any inclination to pretensions—pretensions to force, to

success, to grace, to health, have your photographs taken. Have your photographs taken! There are great preachers in the world, but none of them will repeat so plainly the *solve senescentem* of Horace; none of them will tell you so bluntly: "Look you, my good man, take your harness off, put water in your wine, give up all idea of being brilliant, content yourself with being good, useful, and humane." That belongs to all ages.

Old age has a beautiful part to play; it is not to counterfeit youth, it is to love it, and, in turn, to be esteemed by it. Old age may, perhaps, possess its charms; but they are charms that are serious, and, above all, disinterested. All young people are more or less usurers; their amiability, their elegance, even their joyfulness, always bear some resemblance to investments: they put out their smiles at interest. Let the old man do precisely the contrary; it is not forbidden him to endeavour to please others, but with the condition of never thinking of himself. Let him take for model the charming Ariste, in Molière's "School for Husbands," who is amiable, graceful, smiling, gallant even, and who is never ridiculous. Why? Because he gives everything, and asks for nothing.

This is what this photographic album said to me, and it is, certainly, very good advice; but it, also, requires advice. When we speak so plainly the truth to others, we must permit the truth to be spoken to us.

(To be continued.)

## Recent Patents.

### OBTAINING PHOTO-METRIC MEASUREMENTS.

BY F. J. BOLTON AND C. E. WEBBER.

The specification runs as follows:—

"It is known that certain bodies, when exposed to light of greater or less intensity, become changed in their electrical conductivity or resistance.

"According to our present invention we apply this principle to the measurement of light and of the comparative transparency or density of translucent substances in the following manner:—We place the body to be acted on by the light in an electrical circuit, in which circuit there is also placed an electrometer or other known gauge of electrical resistance. On the body thus placed in the electrical circuit we direct the light, the value of which is to be measured; or we direct light passed through the substance whose transparency or density is to be tested, and we employ the measurement of altered conductivity or resistance of the body furnished by the electrometer or other gauge, as an index of the value of the light, or of the alteration to which light is subjected by the interposition of the more or less transparent or dense substance through which it is passed.

"It will be understood that by this method and apparatus photometric measurements may be obtained in terms of electrical measurement."

### IMPROVEMENTS IN PHOTO-LITHOGRAPHY.

BY ALFRED SLATER.

The following methods of producing an image on a lithographic stone received provisional protection only:—

"This invention relates to the art of reproducing copies of photographs in the printing press from an ordinary lithographic stone.

"The processes consist—

"First. From a photographic negative I obtain a picture in gelatine leaf or other substance by processes known; then I pass two inking rollers with lithographic printing inks of different densities over the leaf, and then I take or pull off from the leaf an impression or picture on lithographic transfer paper. I then transfer the impression from the transfer paper to a lithographic stone, from which impressions can be pulled as desired.

"Secondly. When the picture or impression is obtained in leaf I embed it into type or other similar metal by pressure as at present practised, thereby leaving a print. I then ink this print and pull off an impression on to lithographic transfer paper, and transfer

the same to a lithographic stone, from which impressions can be pulled as desired.

"Thirdly, I obtain an undeveloped picture on a film of gelatine mixed with alum or other similar substance, which, as already known, renders the film so that when exposed to the action of light through a photographic negative a picture is obtained, the picture being absorbent to the degree acted upon by the light, and the grounding non-absorbent; the former absorbent of greasy ink, and the latter non-absorbent of greasy ink, but absorbent of water. I ink this film with two rollers having inks of different density, and pull off an impression or picture on lithographic transfer paper, and then transfer the impression to a lithographic stone, from which impressions can be pulled as desired."

#### WESTON'S BURNISHER FOR PHOTOGRAPHS.

THE following specification describes details of Weston's press, which produces a fine surface by burnishing, rather than merely pressing, the card. It is as follows:—

"The object of the said invention is the production of a machine which will give to photographs and other like articles a durable polished surface. This object is effected by the application of heat and friction to the article under pressure. I use a bed piece, to which the apparatus is attached; the same is provided with means for securing it to a bench or table. I construct a convex bed of wood or other suitable material, upon which the photograph or other article is laid face upward. On the aforesaid bed plates are standards having slots at the top, through which passes a rod or bar; to this rod is securely attached the burnisher made of metal. I prefer to have it of cast iron, with its lower edge, which is turned up and concave to fit the convex bed case, hardened and highly polished. Set screws are fixed in the top of the said standards, and by turning them down they press upon the aforesaid rod, and force the burnisher attached to it down upon the bed. I attach to the said rod a lever, by which a to-and-fro motion is given to the burnisher. This lever has its fulcrum in the bed piece. The burnisher is heated by a lamp. Five minutes are usually required to heat the burnisher sufficiently. The picture being placed upon the bed, face upward, the burnisher is forced down by the aforesaid screws, and by means of the lever is moved over it. One or two strokes will be usually enough to impart a brilliant finish.

"A like effect may be produced if the burnisher is stationary, and the picture moved over its face, the principle being the same in both arrangements. In the latter case the burnisher has a convex roll revolving upon a shaft in standards placed over it. The burnisher is horizontal, and the picture receives its pressure from a set screw placed under it. A lamp supplies heat, as before, and the picture being inserted between the roll and burnisher the former is revolved by the crank, and the picture receives its polish as it passes through the machine."

#### PHOTO-MECHANICAL PRINTING.

BY CAPTAIN W. DE W. ABNEY, R.E.

THE following specification contains details of Captain Abney's patent improvement in photo-collography. It is as follows:—

"My invention consists of an application of the well known fact that a solution of gelatine or other gelatinous substance when mixed with a suitable proportion of an alkaline bichromate and dried is rendered insoluble in water by exposure to light. Also, further, on the fact that gelatine treated in this manner will take a greasy ink even after being soaked in or brought in contact with water in proportion to the degree in which it has been rendered insoluble in or repellent of water by exposure to light.

"In order to carry out my invention I take a sheet of paper of any suitable size, and I float it for from one to three minutes on a warm solution of gelatine and bichromate of potash in water, the gelatine being swelled and dissolved by the aid of heat in the usual way. The proportions of these ingredients vary according to temperature and the subject that is to be copied, but the formula which I prefer to use is as follows:—

Gelatine ... ..	3 ounces
Bichromate of potash ... ..	1½ "
Water ... ..	50 "

"I then hang up the sheet of paper so coated to dry, and when dried I repeat the operation and hang it up to dry again by the reverse end. I sometimes treat the paper as before described with

a solution of gelatine without the addition of bichromate of potash, making a stock of gelatinized paper which will keep indefinitely, and when required for use I float this prepared paper on a solution of bichromate of potash of about thirty-five grains of the salt to the ounce of water, and dry. Sometimes I give the paper a preliminary washing of gelatine to which has been added a sufficient quantity of alum or other substance which will render gelatine insoluble; or I coat it as first described, and I then render it insoluble by the action of light, and then coat it again as before described. The object of this is to get a fine surface on which the final sensitive gelatine film shall rest.

"The methods described are well-known and practised in photolithography.

"I next take a negative of a true subject in the ordinary manner, and place it, in the method well understood and practised, in contact with the prepared paper, which is then exposed to the action of light. Where the light acts through the transparent parts of the negative there the gelatine, as before stated, becomes insoluble, and it also becomes discoloured to a brown tint. When I judge the picture to be sufficiently printed I take the paper upon which a picture has thus been printed, and I place it in a dish of cold water, or else in cold water to which a sufficient proportion of alum or any salt which renders gelatine insoluble has been added. I then wash out a good deal of the bichromate of potash which has remained unaltered, a portion of which, however, I prefer to leave in the gelatine. When the paper on which the picture has been printed is thoroughly soaked I take it and place it on a flat support of zinc, pewter, glass, or other suitable material, and I get rid of all superfluous moisture, either by placing it in a press, drying it with blotting paper, or leaving the moisture partially to evaporate by any other convenient means. I then take a soft roller, such as that used in producing the pictures known as heliotypes, and described in the specifications of the letters patent granted to Ernest Edwards, dated December 8th, 1869, and numbered 3513, and dated September 15th, 1870, and numbered 2485, and dated October 20th, 1871, and numbered 2799, and dated January 9th, 1872, and numbered 73, and having coated the roller with transfer ink of the kind ordinarily used by lithographers, or with any other suitable greasy ink, I roll it over the surface of the picture. Upon the parts of the picture where the light has acted, and which are consequently repellent of water, the ink will adhere, whilst upon those portions which have been unacted upon, or only faintly acted upon, by light, the ink will not adhere. If the negative be thin (as understood by photographers), and thus cause what should be unaltered gelatine to become slightly altered by the light, a stiff or thick ink on the roller will prevent these portions being covered by the ink, as it will only permanently adhere to those parts strongly acted upon by the light, as explained in the specification of the letters patent of Ernest Edwards, dated December 8th, 1869, and numbered 2543, already referred to. When it is judged that sufficient ink has adhered to the picture I remove it, and if thought advisable I place it for a short time in alum and water. This is not necessary, but may be advisable in certain cases. I then dry the inked up picture thus produced, and if the bichromate of potash has not at all been washed out in the previous washing described, I prefer that actinic light should be allowed to fall on the surface of the print to harden it, and thus prevent the film adhering to the stone or metal plate, to which, after re-damping, it is to be transferred for the purpose of printing from in the printing press. Instead of paper as a support for the gelatine film I sometimes use fine woven calico, linen, india-rubber sheeting, silk, or other suitable analogous material. There is now a complete picture in greasy ink ready to be transferred in the ordinary manner to stone or metal plates for the purpose of printing from.

"I claim as a novelty the method of 'inking in' such a transfer on gelatine or other colloid body for the purpose of being transferred to stone or metal plates, substantially as described, as being different in all essentials to any process yet published.

"If a 'half tone' negative be employed, the paper may be used for obtaining pictures in ink as by the heliotype process already referred to, or by any other of the methods well understood and practised. In such a case I prefer to coat the back as well as the front of the paper with gelatine to cause it to adhere to the support. The front of the paper which is to be in contact with the negative should have a thicker coat than if the picture is to be used for a transfer as above described.

"Another modification of my invention which I sometimes employ is as follows:—I coat a sheet of paper or other suitable material with a solution of gelatine in the manner hereinbefore described, but I omit from such solution of gelatine the bichro-

mate salt, and I only add a small proportion of alum or other substance which has a tendency to harden the gelatine or render it insoluble. Upon the sheet thus prepared I write or form designs by means of any kind of pen or other suitable instrument with an ink composed of a gelatinous solution, or solution of gum, to which has been added a proportion of a suitable bichromate sufficient to render such ink sensitive to light when dry in the manner hereinbefore described. I sometimes also add to the ink thus prepared a quantity (in any convenient proportion) of aniline dye, preferably of a mauve colour. When the writing or designs thus formed have become dry, and have been rendered non-absorbent of water by the action of light, I damp the sheet, and then ink it up by means of a roller in the manner already described, and the writing or designs can then be transferred to stone or to a metal plate for the purpose of printing from in a printing press."

### DURABLE SENSITIVE PAPER.

BY DR. J. SCINAUSS.\*

It has long been the desire of the manufacturer of photographic papers to produce a durable silver paper which might be especially useful to amateurs. Professional photographers are less interested in the matter, for they are, as a rule, contented if their paper lasts them a few days without turning yellow. Only at rare intervals does the wish to possess sensitive paper capable of lasting for months spring up in their breasts. A long row of recipes have been published during the last few years for preparing a material of this kind. Precautionary measures, such as the employment of an air and light-proof box, provided with chloride of calcium, have been suggested; a carbonate of silver paper has come to us from Paris; and, finally, there is the method before us of washing and fuming albumized paper, as suggested by M. Baden, which is found to be of a most practical character.

Recently, I received from a friend in England a durable sensitive paper which put into the shade the qualities of other papers of this kind, for it was very sensitive, and, after a long period of keeping, scarcely altered in appearance; after printing and fixing, the whites of the picture were faultless, and the prints could be touched easily and beautifully in any of the ordinary gold baths. It was free from blemishes and blisters, and, in a word, behaved like a sample of the best albumized paper. Unfortunately, I received but a third of a sheet for experiment, and the preparation collected from the surface of it would scarcely have covered the tip of a penknife. This, owing to the different salts and organic substances added, could not be satisfactorily analysed, despite the great care taken, so that I must await a further supply before I can undertake any other examination. In investigations such as these, experiments by comparison are unreliable, and sometimes only prove the truth of one's analysis from the fact that in the latter, the presence or absence of certain constituents can be proved, which are present in appreciable quantities, but it is not shown in what manner, or in what order, the constituents have been applied to the paper—a matter, of course, of the utmost importance in practice. I may be permitted, however, to give, at any rate, the nature of my experiments, and communicate some of the results about which there is no doubt.

Upon putting the sensitive paper into water, it appears, especially from the back, to become very transparent, as if it had been worked in an unsized state. The reaction of the wash water is slightly acid, and betrays no coagulation on boiling to precipitate the soluble albumen. To precipitate the soluble silver salt, it was treated with hydrochloric acid, and the slight amount of chloride of silver was separated by filtration, and treated with sulphuretted-hydrogen water. No precipitate was apparent. Supersaturated with ammonia, the solution, on treatment with sulphide of ammonium, gave a slight iron reaction, and

some phosphate of lime, presumably from the albumen, as the solution was acid. Carbonate of ammonia added to the filtrate gave no remarkable reaction. After drying of a portion which had been treated with hydrochloric acid, calcining the residue gave a notable reaction upon soda by antimonious potash, and on drying, crystals and cubes of chloride of sodium appeared. A portion of the dried, but not calcined, residue, treated with caustic potash, and warmed, gave strong vapours with hydrochloric acid—ammonia, which could also be sublimed as chloride of ammonium.

The testing for acids was the most important, as also the most difficult, as it was here a question principally of organic, and not volatile acids, whose action is not very marked, especially when several of them are present. As it is well known that an addition of citric acid to the albumen silver bath preserves the paper, and as the preliminary experiment proved the existence of an acid body, I directed my attention more especially to the detection of citric and similar acids. Some time ago the employment of different organic acid silver salts was employed with advantage for paper printing, besides the citric acid, tartaric, and formic acids giving sensitiveness and beautiful tones. To preserve these qualities, together with those possessed by ordinary chloride of silver paper, it is only necessary to add a little citrate or tartrate of soda to the chloride of sodium or ammonium used in albumenizing the paper. Citric acid alone is, as a matter of course, powerless to precipitate nitrate of silver, but there is necessary, besides, an alkali, which, in the double decomposition, attaches itself to the nitric acid. But both in acids and ammonia, citrate of silver is soluble, a fact deserving of notice.

To return to the testing of the paper in question. I thought over all sorts of ways for the purpose of securing all the substances, and even the unknown ones, in solution. In the first place, I digested the paper with dilute soda solution, in this way separating the silver in the form of oxide, and dissolving the albumen as well as most of the other substances. To separate the albumen, the dilute solution was treated with dilute citric acid, warmed and filtered, a portion of the precipitate being treated with nitrate of baryta, which proved the existence of sulphuric acid, although not as an essential constituent. The remainder of the fluid was neutralized and supersaturated with lime water. Some flocculent matter which here showed itself appeared to demonstrate the presence of tartaric acid; the direct proof of the existence of this body, however, by means of acetate of potash, was not decisive, for the small amount of precipitate was always flocculent and not crystalline, as is the case with tartrate. After filtering and boiling the solution, supersaturated with CaO, a precipitate was formed, which might be looked upon as citrate of lime. The original paper, as also the residue of the dried extracts, blackens easily when warmed with sulphuric acid, a fact which seems to tell of the existence of citric and tartaric acids.

The testing for volatile organic acids was, by reason of the great excess of nitrate of silver or nitric acid present, very difficult. The testing for saccharine, and other similar neutral organic bodies, was also uncertain, as by the Trommer method every trace of iron must first be removed.

The following substances were proved to be present in the paper:—Albumen, chloride of silver, nitrate of silver, soda, ammonia (most likely from the salts in the albumen), nitric acid, citric acid and traces of sulphuric acid, phosphate of lime, and oxide of iron.

As above stated, the citric acid may be added—if there is a sodium compound—to the albumen of the paper, or to the silver bath, or employed in a special bath before or after sensitizing. We should think that the paper would be more durable if the acid were added in the last named manner.

## THE PHOTOGRAPHIC SOCIETY.

THE new laws, a draft of which was sent to each member, to the general purport of which we referred in our last, have now been accepted as the code of regulations for the government of the Photographic Society, which, in the new laws, is styled the Photographic Society of Great Britain, instead of the Photographic Society of London, as heretofore. It is, beyond a question, matter for grave regret that the meeting at which the draft was accepted, and acquired the force of law, was not more numerously attended; but it is foolish to refer the sparse attendance to remote, improbable, and inoperative causes, when a very simple and manifest cause is at hand. The members generally are sick and weary of discussion on points of government, in which they feel little interest, and which in no wise affect the actual business and influence of the society. Under the old somewhat clumsy and imperfect code of laws, the society had passed through almost every phase of history: the early success which indeed premature extravagance, followed by failing success and straitened means; then the energetic action which breasted the difficulties of the position, and recovered a position of more than solvency and increased usefulness. And, so far as it is possible to ascertain, neither the failure, nor the recovery from the failure, were in any degree attributable to the laws. Nevertheless, the laws were open to amendment: the revision has received careful attention, and they are accepted by a special meeting consisting of less than a score of persons. The council, who, whether new or old, by the late disturbances have been kept at thankless work beyond all reason, were in attendance to the number of thirteen or fourteen, and found assembled for the business of the special meeting four persons! One gentleman found in this circumstance a ground for blaming the acting honorary secretary for not having sent out special post cards, calling members to the meeting, the announcement in the Journal of the society, which constitutes its special organ, being deemed insufficient, because many of the members, it was said, never open it! Apart from the culpable indifference which such a statement charged, Mr. Hooper's answer was completely to the purpose: the announcement of the meeting had been made not simply in the society's Journal or "Transactions," but in both the independent journals, one or other of which was read by every photographer. Mr. Blanchard, with a happy spirit of optimism, concluded that the absence of members generally was simply an indication of complete confidence in the executive. Possibly this is partly true; and to such confidence on the one hand, and to weariness of the subject on the

other, the sparse attendance was due. At any rate, the chairman, as in duty bound, proceeded with the business, and Mr. Bird, shrewdly pointing out the fact that the whole code would be open to challenge at the annual meeting next February, if any one felt interested to discuss the question in detail, moved the acceptance of the proposed laws *en masse*, a proposition which was adopted. If any improvements worth discussing are discovered by any member, he will be at full liberty to bring the subject before the annual meeting, provided he give a month's notice of his intention to re-open the subject. Till then, at least, it is to be hoped that the society will enjoy some respite from worrying squabbles. One gentleman, it is true, who has been associated with the malcontents, hinted the probability of further agitation, and by his remark of uncertain application, to the effect that "the same spirit was at work," drew from the chairman the quietly quaint reply, "So it seems." We will hope, however, that the genial summer influences, with the perfect rest which is often one of the most potent remedial agents in case of constitutional disturbance, will remove inflammation, and restore strength and tone to the society.

The society has other and more important business. Not least amongst the good works it has for some time effected has been the holding of an annual exhibition, which has done more to promote the production of good work, and stimulate advancement generally, than any other agency we know. The prospects of the present year's exhibition have been seriously perilled by the waste of time in petty agitation. But the council have resolved to make an effort to hold an exhibition and secure success. The old traditions of hard work still prevail in the council, and a committee has undertaken the task of making all preparations for the exhibition, and duly advertising members of all details. To secure a good exhibition will do more for photography than to lead a hundred emeutes in the society, with or without reason; and we hope that, though somewhat late, contributors will, by additional effort, prevent the recent time-wasting agitation from injuring the exhibition. More effort will probably be necessary, but we hope the effort will be made. As no medal will this year be given, every effort must bear the credit of a labour of love.

## WASHING PRINTS.

WE have been, during the last few months, several times personally consulted by photographers in large practice as to the probable cause of early fading in their prints, and have almost invariably found, in course of conversation as to the modes of working adopted, that they depended for washing chiefly on long soaking. "It cannot be imperfect washing," is commonly remarked, "for the prints remain in running water all night." Waiving, for the present, consideration of all other causes of fading, we think it important again to call attention to the fact that merely washing in running water is by no means an efficient method of removing hyposulphite, and that long soaking is often, in itself, absolutely injurious, initiating a decomposition in the sizing of the paper which must finally issue in the destruction of the print. As regards the time of soaking, four hours should always be ample. It is rather on the mode of applying the water, than in the time of soaking, that efficient washing depends. Frequent changes of water, and perfect draining between each, will more effectually remove the hyposulphite than much soaking. The use, if possible, of the sponge or squeegee between changes of water, is most desirable. Placing the prints in a pile, and subjecting them to severe pressure once or twice between changes of water, is one of the most efficient plans of all. The use of a *douche* playing upon the prints—a plan adopted by Herr Albert, of Munich—is very efficient. Referring to this plan, which has been adopted by Mr. Kurtz, his mode of applying it was recently described

at the Germau Photographic Association in New York. The plan is as follows:—

"After fixing, the prints are put in a flat trough, the bottom of which consists of grooved plate-glass, and is in an inclined position to allow the water to run off; above this trough are several douches, connected by hose with a water-pipe running along the ceiling. To prevent the prints from being carried away from under the douches by the force of the water, they are put in half cylinders of glass, about twenty inches in diameter for large prints, and glass rods for smaller ones. When placed on top of these they will not move. After being washed on both sides for about five minutes, the silver test for hypo, as lately published, fails to show any trace of it. Generally, after thus washed, the prints are thrown into a tank with running water till the whole lot is got through with."

It will be seen that in all these cases the principle of using either friction or pressure to drive off the clinging hyposulphite is adopted as of vital importance.

#### DR. VOGEL'S DISCOVERY REGARDING THE NON-ACTINIC RAYS.

ON another page we print a brief communication from Dr. Vogel in reply to some of the criticisms upon his alleged discovery of a method of actinizing non-actinic rays, in which, as it appears to us, his arguments are most cogent and will require well considering by those who have concluded that the mistakes, which it is manifest exist somewhere, are accredited entirely to Dr. Vogel. The objections to his announced discovery have been of three kinds. First, it has been urged that the principle which he affirms he has discovered, is improbable *a priori*. To that it is unnecessary to affirm that ninety per cent. of the greatest discoveries made appear improbable, and in many cases impossible, until the discovery is made. Next, it is affirmed that those who have followed his experiments have not met with similar results. To this it is necessary to reply that the argument is at best but of a negative character. Failure in securing results with a perfect method is not uncommon; but it is just as likely that it is due to some imperfection or error in the conditions under which the experiment is verified, as that the original worker misunderstood or misstated his work and its results. This is rendered more probable by the fact that Dr. Vogel has found similar results in over two hundred trials, whilst in many instances those of his critics have not exceeded a dozen. That the conditions may easily be missed is illustrated by the fact that in the plates sent to us by Dr. Vogel, in illustration of his position, we find that a strongly stained film gives barely the trace of an image, whilst, with varied degrees of dilution, as described in his article we now publish, we obtain more and more perfect results, the best giving an unquestionable extension of the ordinary photographic spectrum. Finally, in Dr. Van Monckhoven's courteous paper a suggestion as to the cause of Dr. Vogel's mistake, as it is adjudged, is given. Dr. Vogel has worked, it is assumed, with too wide a slit in his spectroscope for precise definition of the spectral lines, and Dr. Van Monckhoven suggests that the alleged extension of the spectrum is due to reflection or diffusion of the light by the imperfection of the prism employed in forming the spectrum. To this Dr. Vogel very naturally objects that if his results were due to such a cause, they would be equally produced upon any sensitive plate, whilst his extended spectrum is only obtained upon the plates suffused with colour as he has described.

As we have said, the plates forwarded to us bear out the assertions of the author of the discovery. A narrower slit on the spectroscope would, undoubtedly, have given finer definition of the lines in the spectrum, and we hope to hear of a repetition of the experiments under those pre-

cise conditions which Dr. Monckhoven suggests. In the meantime we shall have pleasure in showing the plates to any one interested in the question. If further experience verify Dr. Vogel's discovery, it is a question of much wider interest than is involved in its relation to spectrum photography: it comprehends, in fact, the possibility of a practical subjugation of all the disabilities in relation to colour which have hitherto limited and crippled the operations of the photographer.

#### THE PARIS PHOTOGRAPHIC EXHIBITION.

The following awards have been made by the jury:—

*Grand Silver Medal*.—M. Rousselon, Paris.

*Medals* (first section).—W. Bedford, A. Braun, F. Luckhardt, Lumière, J. J. Rodrigues, Rommler et Jonas, Rutherford, Thiel aîné et Cie, Victoire.

*Medals* (second section).—E. Baldus, Barkanoff, Bingham (late Ferrier, Lecadre, et Cie), K. Brandel, Chambay, Derogy, W. England, Ermakow, G. Fortier, Gertinger, Geymet et Alker, Jules Girard, Gougenheim et Forest, D. Hedges, Johnson, C. Koller, Knebel, Lachenal, Favre et Cie, Lafon, Lefinan et Lourdel, V. Lévy et Cie, A. Liébert, Maes, A. Magny, Mathieu-Déroche, Quetier et Cie, Achille Quinet, Ravaisson, A. Reds, C. Relvas, C. Reutlinger, Rottmayer, Comte de Roydeville, L. Vidal, Waléry, Woodbury.

*Honourable Mentions*.—Benoist, Brignoli, Brownrigg, Cadot et Delaunay, H. Denier, Diston, Fleury-Hermagis, H. Günzel, Ch. Goudy, Haieque de Saint-Senoeh, Hermann, L. Hervé et Ch. Perier, Jacobi, C. Knudsen, Lambert et Cie, Mage, Mayssl, Mlle. R. Mezzara, S. Pector, Pinel-Pécharrière frères, Piquée, R. Rive, M. Rupprecht, Schultz, Strumper et Cie. Szacinski, J. Ungar, G. Wolf et Cie.

#### A NEW PHOTO-ENGRAVING PROCESS.

AT the last sitting of the Academy of Sciences in Paris, some photo-engravings were submitted for inspection, produced from copper-plates by means of a *Daguerreotype* impression. The prints are said to be of a favourable nature, and although wanting in some respects, they prove that the method is one worthy of further attention.

M. Bouquet de la Grye is the inventor of this method, and the same may be thus briefly summarised:—

1. A copper plate is covered with a thin film of silver, which naturally is very adherent, and the silver surface is coated with a coloured varnish.
2. A design or drawing of any kind is traced upon the varnish with a fine hard point, exactly in the same way as a diamond is employed for engraving upon stone.
3. The design thus produced—where the varnish has been removed, and the metal laid bare—is etched by means of perchloride of iron.

Instead of tracing with a point as above, however, upon the varnished surface, a *Daguerreotype* image may be produced upon the silver direct, and this is afterwards treated in the same way. The *Daguerreotype* must, however, be the representation of a design, or sketch, in black and white—that is to say, with certain definite lines—otherwise a clear etching cannot be obtained. By employing photography in this connection, it is possible, of course, to produce an enlargement or diminution of any design one may possess.

The plate, having been etched, and treated with acid to render the lines clear, is worked in exactly the same manner as an ordinary copper plate engraving, and printed in the usual press. The silver surface upon the copper contributes to the sharpness of the lines, and in this way a much clearer result is produced than is the case when an ordinary copper plate is employed.

## SENSITIZED ALBUMENIZED PAPER.

At the last meeting of the Photographic Section of the American Institute the president, Mr. Newton, gave some details of his experience in preparing permanent sensitive paper. He said:—

"The preparation of a sensitized albumen paper as a commercial article has not been successful. It has been either too expensive to meet the popular demand, or deficient in keeping quality. There are several ways by which paper can be prepared so that it will keep indefinitely; but, as a rule, it is exceedingly difficult, if not impossible, to make a print on such paper that would not ruin the reputation of any photographer, especially after it is a week old. Some time since, in experimenting in this direction, I found that by floating the albumen paper back down for one or two minutes on a solution of hydrochloric acid—one ounce of acid to forty ounces of water—and drying, it would render it capable of keeping perfectly for ten or twelve days after sensitizing. Not only this, but the prints were remarkably fine, made on paper thus prepared; and, also, those made after ten days' keeping were equal to those printed immediately after sensitizing. Paper so prepared should not be fumed until required for use. After the paper has been removed from the acid solution and dried, it would be well to pack it away under a light pressure, placing the albumen surfaces together, so that when required for use it will be in proper condition to put upon the sensitizing bath. As it is a great convenience for photographers to be able to keep paper for several days after sensitizing without its deteriorating, I would suggest that some of our many manufacturers of albumen paper prepare some of it in this way, as I am sure photographers would willingly pay the extra expense."

"The President exhibited some prints made on paper preserved in this way after having been kept for ten days after sensitizing, which were very fine, and equal to those made on paper sensitized that morning. The silver solution was from thirty to thirty-five grains. The President added: 'In the toning of these prints I used a little tartrate of antimony, and it worked very well. In the first place the prints turned red, a very deep rich colour, and toned up from that. I have not experimented enough to give a reliable formula, but I would suggest half-an-ounce of tartrate of antimony, which is commercially known as tartar emetic, dissolved in sixteen ounces of water; for each grain of gold use half a dozen drops of that solution, and increase it until you get the desired effect.'"

## MODIFIED DRY PLATE PROCESS.

MR. NEWTON, at a recent meeting of the American Institute, described a dry process he had been trying. He said:—

"In experimenting with dry plates, I found a preservative solution as follows,—

Water	...	...	...	10 ounces
Sugar of milk	...	...	...	100 grains
Tannin	...	...	...	20 "
Pyrogallic acid	...	...	...	20 "
Laudanum	...	...	...	1 drachm,

made a very sensitive dry plate. I made some very fine negatives with thirty seconds' exposure. Working in that direction some five years ago, I used to make negatives in fifteen seconds. That was all the time used with my tea plate. But in my experiments at that time I kept no record of the methods I employed, and often found it difficult to recall my formula. In thinking it over, it occurred to me that, in those days, I always used a chloride in my bromo-iodized collodion—one grain of chloride of cadmium to the ounce. The addition of a chloride appears to make them capable of being developed with plain pyrogallic acid. I exposed plates prepared with such collodion five, fifteen, and thirty seconds, and in each instance

obtained good negatives. After exposure, wash the plate thoroughly, and flow with a solution of pyrogallic acid from one to four grains strong, according to time exposed. The image will immediately appear in outline and detail. When it is sufficiently out, add a small quantity of solution of citric acid to the pyro. solution, and flow off and on a few times; then add a few drops of a ten-grain silver solution, which will bring it up to the required density. The image brought out by the pyrogallic solution is very thin."

## RENDERING ACTINIC NON-ACTINIC RAYS.

BY DR. H. VOGEL.

In the PHOTOGRAPHIC NEWS of June 12th I find an editorial notice\* of a communication from Dr. Van Monckhoven,

\* The original paper of Dr. Monckhoven is not yet in my hand, who has repeated my experiments on the action of colours on the sensibility of bromide of silver. Dr. Van Monckhoven has not succeeded, and he ascribes my results, if I understand aright, to some optical failure of my spectroscope.

I know very well that in each spectroscope are visible secondary images of the spectrum, and I have observed them very often. Generally these secondary images are of feeble light and very different position from the direction of rays falling on the spectroscope. I have studied also the photographic action of this secondary spectrum, and have found it very weak. I could get only an impression of this feeble image on an ordinary silvered wet collodion plate.

It is easy to prove that the strong action I have observed in the yellow of the chief spectrum does not belong to the action of a secondary spectrum.

1. If, indeed, the secondary spectrum, or any optical failure of the instrument, had made the impression I ascribe to the yellow, this impression would have been visible, not only on the coralline coloured plate, but on any other sensitive plate; but I have tried very often one plate immediately after the other, pure bromide plates, red-coloured, and green-coloured plates—and in each case I observed the stronger action of the less refrangible rays in different spots of the spectrum, according to the place of the absorption bands of the admixed pigment.

2. If the action I ascribe to the yellow or red of the spectrum were caused by the blue rays of the secondary spectrum, or any optical failure of the instrument, I could never have obtained the Fraunhofer lines belonging to the yellow or the red. But I have got the Fraunhofer lines belonging to the portions of the spectrum mentioned, and that is the best proof of the action of yellow and red rays.

If I had made only some two, or perhaps twelve plates, there might be possibly an error; but I have made some two hundred plates under the utmost different conditions, and with the same results. I presume that Mr. Monckhoven has coloured his plates too strong. It is a very curious fact I shall explain in the next, that a strong coloured plate does not give the action mentioned.

Herewith I send a set of my original spectrum plates, taken on bromide coloured with naphthaline red.

On Plate 1 (strong coloured) is visible only a feeble action of the blue—nothing in yellow.

On Plate 2 (less coloured) is visible a strong action of the blue, but only a trace of action in the yellow.

On Plate 3 (more or less coloured) is a very remarkable action in the yellow.

On Plate 4 (pale coloured) the action of the yellow rays is nearly the same as the action of the blue ones.

I said, further, that aniline green coloured plates with a visible action on the line C (in the red). Further, a chloride of silver plate (a) coloured with naphthaline red, and with an action stronger in the yellow (line D) than in the indigo (line G). Such an action can never be effected by any secondary spectrum.

At last a Wortley plate, on which I have at first observed

the strange fact that under certain conditions bromide of silver may be more sensitive to a less refrangible colour (green) than to a more refrangible one (blue). Here can be no doubt that the stronger action in green is due to the green rays, and not to the blue rays of any secondary spectrum, for the lines of the green are easily visible.

It is a curious fact that I hear so much objection against my discovery from England, though English experimentalists have a very convenient way to test it. If Colonel Wortley still prepares his plates in the same way as a year ago, everybody can prove my assertions by exposing a Wortley plate to the spectrum. But I would request the use of a *true* spectrum, and not a so-called artificial one—that is, coloured glass strips, which can never give the action of a spectrum.

### Correspondence.

#### PHOTOGRAPHIC PRIZES.

DEAR SIR,—I cannot imagine anything more detrimental to the real progress of photography than the wholesale distribution of prizes mentioned, with apparent satisfaction, by M. Ernest Lacan in the *News* for June 12th. He says there: "The number of medals and honourable mentions awarded, which are nearly equal to the number of exhibitors, tends to confirm what I said in my last letter regarding the exceptional excellence of this exhibition." "If I do not err, every one of them (the English exhibitors) has received a medal or honourable mention." I find by his letter of June 26th that there were eighty-four exhibitors.

What value can the recipient of such a medal or honourable mention attach to his prize? It may be useful for advertising purposes, but it cannot possibly have any other value.

Photographers are constantly complaining that they are not, as a class, placed among "artists" in the estimation of the public. Can it be possible that the public would do anything but laugh at a set of men who accept, and pride themselves upon receiving, such valuable rewards of honour? Such a reckless distribution of prizes is simply ridiculous.

I hope for the honour of photography that the many recipients of these most valuable medals will put them on the fire, and not go about like the tailor in the fairy story, with the grandiloquent declaration on his shield, "I killed seven at a stroke."—I am, sir, yours truly, N.

#### SENSITIVE GELATINE PELLICLE.

SIR,—Will some of those gentlemen who have tried and succeeded with Mr. Kennett's gelatine pellicle be kind enough to give us their experiences—*i. e.*, the difficulties they have encountered, and how those difficulties have been surmounted? My own experience has been as follows:—

1. I have found the pellicle exceedingly sensitive—quite as much so as wet plates—and I believe that it has the power of rendering the deepest shades perfectly.

2. I have found considerable difficulty in intensifying the image, and I should like to know whether this is a defect in the process.

3. I have found that the films are *extremely* liable to stain—especially the nearer you approach the end of intensifying—and herein (the staining) lies, I should think, the greatest drawback to the process. Of course extreme care may obviate this; but the slightest fault may immediately destroy an otherwise first-rate negative.

4. There is a certain amount of difficulty in obtaining an even film to start with; but that is purely mechanical, and can be obviated.

5. I am of opinion that the process has promising qualities; but, as an old hand at dry plate processes and alkaline development, I am constrained to say that it is the most difficult to work that has ever come under my notice.

May I add, in conclusion, that Captain Abney's beer process is really first-rate—easy to work, very sensitive, and satisfactory in its results.—I am, sir, your obedient servant,  
A DRY PLATE.

[We know that Mr. Kennett is more concerned that his pellicle should be deserving of success than for mere success itself, and that he will not only be anxious to assist those who are working it through any difficulties, but will be glad that the question should be honestly discussed. We shall be glad, therefore, to receive brief, clear, and courteous statements of experience.—Ed.]

### Proceedings of Societies.

#### PHOTOGRAPHIC SOCIETY OF LONDON.

A SPECIAL meeting of this society was held on Tuesday evening, the 30th ultimo, in the Architectural Gallery, for the purpose of passing the new laws, a draft of which had been placed in the hands of each member. Mr. J. SPILLER, F.C.S., in the chair. Minutes of a previous meeting having been read and confirmed,

The CHAIRMAN said that the new draft of laws, to the preparation of which the council had given very careful attention, having been placed in the hands of all the members, it would not be necessary now to read them. He would simply place them before the meeting, and take a vote upon each, *seriatim*.

Mr. HUGHES said that as there were only three or four members present besides the council, it was practically a council meeting, and the passing of laws was too important a matter to be decided under such circumstances. No post-cards had been sent out with the announcement of the meeting; the intimation that such a meeting would be held being only given in the society's Journal, which few people opened, members probably did not know of the meeting. Besides, it was always difficult to get a good meeting together in June. He should propose that the consideration of the laws be postponed.

The CHAIRMAN said the meeting had been duly announced. The regular June meeting had been really one of the largest they had ever had, and he himself at that meeting had stated that the members would be shortly called together to consider and pass the laws, then nearly ready.

Mr. HENDERSON seconded the motion for postponement.

Mr. H. P. ROBINSON said that he had come expressly from Tunbridge Wells to attend this special meeting for this special purpose, and he did not think that the absence of members who did not feel enough interest in the matter to attend ought to influence the proceedings.

After some conversation as to whether the members had full opportunity of knowing of the meeting, in which Mr. Dallmeyer, Mr. Dymond, the Chairman, and others took part,

Mr. HOOPER, as acting secretary, said that every member had received full intimation of the meeting, which was prominently announced in the Journal, which, with draft of the new rules, was sent to every member. An intimation was given at the last meeting, which was a full one, to the effect that a meeting would shortly be called, and members having any interest in the question would doubtless have looked to their Journals and become fully familiar with the fact. But not only was the announcement made in the Society's Journal, it was announced in the two weekly journals, one or other of which everybody read. Any statement that members had not full means of knowing of the meeting was trivial and childish.

Mr. BIRD said it was certainly to be regretted that a fuller attendance was not present to consider the laws. He could state that the draft had been made carefully, and without any kind of personal bias; but still there were points upon which he should have been glad to have had the opinion of a full meeting. As it was, he thought the simplest plan would be now to pass the laws as a whole, and any point requiring revision could be fully considered at the annual meeting. This would be better, he thought, than leaving the whole question in suspense until that time. He hoped, therefore, Mr. Hughes would withdraw his motion.

Mr. HUGHES urged his motion.

Mr. DAVIES seconded Mr. Bird's motion. The matter could be fully discussed hereafter, if necessary; but he thought that this need not be expressed in the motion, which should be simply to the effect that the laws be passed as they stood.

Mr. BLANCHARD thought that the non-attendance of members was in one sense a very high compliment to the council, and showed that they had full confidence in the laws they had drafted. Feeling that there was no need to discuss them, members simply left them to be passed.

Mr. HOOPER took a similar view. Non-attendance showed two things: the members were sick of having their time wasted on merely business considerations in which they had little interest, and had perfect confidence in their council, to whom they left the matter.

The CHAIRMAN then put Mr. HUGHES' motion, which was lost—himself, his seconder, and another only voting for it.

The CHAIRMAN then put the motion that the laws be passed *en masse*.

Mr. DYMOND said that the laws were open to verbal improvement. The first law, for instance, was not specific enough. It did not say by whom some vice-president or member of the council should be appointed to preside in the absence of the president. He should move, as an amendment, a verbal alteration, making the matter more definite.

Mr. HUGHES said that the rules did not, in many respects, meet the wishes of many members of the society whom he represented. There was no provision for a chairman at all in the absence of all the council, a thing which happened when, at a recent meeting, all the council left the room.

The CHAIRMAN said that even on that occasion all the council did not leave the room. But he must ask if Mr. Hughes, in these remarks, intended to second Mr. Dymond's amendment.

Mr. HUGHES said no; he simply intended to challenge everything he could.

The CHAIRMAN said as the amendment was not seconded, he would simply put the motion that the laws be passed, which was carried.

Some conversation followed on the question whether the discussion of the laws at the annual meeting was to be made compulsory, or merely left to the motion of any one anxious to raise the question at that time; but no resolution on the subject was passed.

The CHAIRMAN said that as in the new laws the treasurer was not included in the eighteen members of council, another vacancy existed; and as Sir Charles Wheatstone was next on the ballot, he announced him as the new member of council.

The CHAIRMAN then announced that an exhibition would be held as usual, the time and place of which would be duly published.

The CHAIRMAN next announced that Mr. Richard Friswell, F.C.S., had been elected by the council as secretary and editor. He added that the society were much indebted to Mr. Hooper for his able services in the interregnum. The council had already passed a vote of thanks to him, and he now asked the meeting to do the same. This was done by acclamation, and the proceedings terminated.

#### AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of the council of this society was held on the 27th inst., at 12, York Place, Portman Square, the Right Honourable the EARL of ROSSE in the chair. The minutes of the last meeting having been read and confirmed, the SECRETARY laid before the meeting the pictures for the current year, and Mr. GLAISHER read his report upon them, of which the following is an abstract.

"After a good two days' work in examining and classifying the pictures for this year, the first thing that suggests itself to one's mind is the large proportion of good pictures, and the small number of inferior ones. It is no unusual thing to have more pictures worthy of prizes than there are prizes to award, but this year we note no less than sixty-eight, which I may call should-be prize pictures, and which demand our special and careful consideration. This very large number of first-class pictures is almost unprecedented, and shows a healthy vigour in our no longer young society, which cannot but be gratifying to our Royal President and the members of the council, most of whom have been with us from the beginning.

"I notice with pleasure that Mr. Hobson, though so good last year, is this year better still, and must now rank as one of our most accomplished photographers. Mr. Beasley and Mr. Murray again compete for the dry plate prize, but the latter gentleman, though quite equal to last year, is now surpassed by Mr. Beasley, whose works this year take precedence, not only of the dry plate pictures, but all the wet plate ones also.

"Mr. Ravenshaw's Indian views are perfect gems. Captain

Lewis again sends us some very interesting studies of prison life. Col. Roche, whose pictures last year were wanting in vigour, now steps into the very foremost rank. Captain Layton, although perhaps still falling short of a prize, sends us some views of great artistic merit. From Sir Joslyn Coghill we have a series of charming Swiss views; whilst Captain White and Major Allen still keep the high position they have held for some years past.

"I notice also some of our new members, whom we may welcome as acquisitions to our society, amongst whom I may mention Mr. G. Brewis, Captain Toke, Mrs. Hancock, and Mr. Milne."

Class 1 contains ninety-four pictures contributed as follows:—J. H. Ravenshaw, 15; F. Beasley, 13; Sir J. Coghill, 9; Captain White, 8; Major Allen, 6; Col. Roche, 6; W. S. Hobson, 5; R. Murray, 4; Captain Lewis, 4; G. Brewis, 4; J. W. Richardson, 3; Rev. W. E. Hancock, 3; Captain Toke, 3; Captain Layton, 2; J. McAndrew, 2; Mrs. Hancock, 2; D. Knapping, 2; W. G. Hunter, 1; T. Brownrigg, 1; and R. O. Milne, 1.

Class 2 contains one hundred and fifty-nine pictures contributed as follows:—J. H. Ravenshaw, 23; F. Beasley, 16; Rev. W. E. Hancock, 12; Captain White, 11; Captain Toke, 10; T. R. Shervington, 7; J. McAndrew, 7; W. S. Hobson, 6; S. G. B. Wollaston, 6; D. Knapping, 5; Captain Layton, 5; Major Allen, 4; N. M. Settna, 4; Col. Roche, 4; G. Brewis, 4; R. Roberts, 4; Sir J. Coghill, 3; R. Murray, 3; W. G. Hunter, 3; J. G. Hyde, 3; Gen. Sladen, 3; R. O. Milne, 3; A. Suzanne, 2; J. W. Richardson, 2; Captain Lewis, 2; Mrs. Hancock, 2; J. C. Stenning, 2; T. Brownrigg, 1; J. H. Ritchie, 1; and Captain Fox, 1.

Class 3 contains 169 pictures contributed as follows:—J. W. Ravenshaw, 15; T. R. Shervington, 12; Rev. W. E. Hancock, 12; S. G. B. Wollaston, 11; F. Beasley, 10; J. H. Ritchie, 9; Capt. White, 8; Capt. Layton, 7; Mrs. Hancock, 6; J. C. Stenning, 5; J. W. Watling, 5; J. McAndrews, 5; R. Murray, 5; Rev. T. F. Ravenshaw, 4; A. Suzanne, 4; J. G. Hyde, 4; E. Milson, 4; General Sladen, 4; D. Knapping, 4; Capt. Toke, 4; Sir J. Coghill, 3; Capt. Fox, 3; K. Roberts, 3; R. O. Milne, 3; J. W. Richardson, 3; N. M. Settna, 2; Col. Roche, 2; Mrs. Fox, 2; G. Brewis, 2; Capt. Lewis, 2; W. G. Hunter, 1; T. Brownrigg, 1; W. S. Hobson, 1; G. W. D. Green, 1; Mrs. Welbourne, 1; and Rev. H. Palmer, 1.

The remainder of the pictures are comprised in Classes, 4, 5, and six.

The following prizes were then awarded:—

First prize, F. Beasley, for Nos. 36, 14, and 24—a large silver goblet.

J. H. Ravenshaw, Esq., for Nos. 251, 261, and 265—a silver goblet.

W. S. Hobson, Esq., for Nos. 103 and 105—a silver mounted claret jug.

Col. Roche, for Nos. 32 and 34—an oil painting in gilt frame.

Sir J. Coghill, for Nos. 11 and 14—a large album handsomely bound in morocco.

Capt. White, for Nos. 57 and 77—a graphoscope.

Major Allen, for Nos. 144 and 148—an oil painting in gilt frame.

D. Knapping, Esq., for Nos. 12 and 14—a large album handsomely bound in morocco.

J. McAndrews, Esq., for Nos. 25 and 28—a graphoscope.

T. Brownrigg, Esq., for No. 4—an oil painting in gilt frame.

G. Brewis, Esq., for No. 126—a large album handsomely bound in morocco.

Capt. Lewis, for No. 52—an album handsomely bound in morocco.

R. O. Milne, Esq., for No. 2—an album handsomely bound in morocco.

Capt. Toke, for No. 10—an album handsomely bound in morocco.

R. Murray, Esq., for Nos. 81 and 82—an oil painting in gilt frame.

Certificates of Honorable Mention were awarded to W. G. Hunter, Capt. Layton, J. W. Richardson, Rev. W. E. Hancock, and Mrs. Hancock.

A. J. MELLIUSH, Hon. Sec.

#### THE PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.\*

THE usual meeting was held May 5, 1874: president, H. J. NEWTON; secretary, O. G. MASON. The minutes of the last meeting were read and approved.

\* Condensed from *Anthony's Photographic Bulletin*

Mr. HENRY T. ANTHONY read from the PHOTOGRAPHIC NEWS of March 27, 1874, an article on "The Reproduction of Negatives."

Mr. BIERSTADT exhibited a negative which he had produced by the directions given, except that he had found it necessary to add a great deal more glycerine. He used 30 drops of glycerine to 100 grammes of the mixture, our atmosphere being so dry. He considered it a very simple process.

Mr. ANTHONY also read from the PHOTOGRAPHIC NEWS of April 2, 1874, Mr. Grogson's article, "On the Elimination of Hyposulphite from Negatives."

Mr. MASON. I remember that some years ago I made some large negatives for Mr. Rutherford's observatory from some positives of the moon which he had prepared. Some two or three years afterwards we found those positives entirely ruined. They had been varnished. The film was covered with peculiar markings, in which were countless little globules, such as we sometimes see on spider webs early in the morning from the dew, very fine and irregular forms, something like honey-comb. I think that since then Mr. Chapman has invariably sealed the negatives in balsam. I attributed that, and so did Mr. Rutherford at the time, to the presence of hyposulphite, probably from insufficient washing.

Mr. BIERSTADT. Were those markings ever seen on anything but plate glass?

Mr. MASON. I cannot say, because plate glass is invariably used for that work.

Mr. BIERSTADT. I have found that plate glass always works in that way, but any other glass never does, whether varnished or unvarnished; and plate glass is unreliable to keep for any length of time.

Mr. C. B. BOYLE. Plate glass is ground, while the other glass has a hard surface. A fire surface is always the best surface.

Mr. BIERSTADT. The surface produced by grinding does not work well for a negative; the natural surface, not ground or polished, is better.

Mr. CHAPMAN. All the glass that we use is ground flat. We have a great deal of difficulty about the glass sweating on the varnished side; some think that it is on account of soda in the glass. When this hard fire film is ground off, it presents a softer interior, and the soda in the glass attracts the moisture, and there is a condensation upon it, which cannot be prevented in any way that I know of. I have had no negatives or positives for the last four years which caused difficulty by cracking. Those that Mr. Mason spoke of were made on glass which was not albumenized. I have plenty of albumenized plates which have been standing for four years, and which do not seem to have been affected. I presume that effect which he speaks of was produced by insufficient washing.

Mr. HUDSON. When the surface is ground, some parts will be harder than others, as with steel.

Mr. J. B. GARDNER. I have a large number of negatives made on plate glass thicker than is commonly used, such as is used for large windows. I bought nearly two tons of that glass in strips just large enough to cut up to the size I wanted. I have several thousand negatives on that glass, and I have found invariably that the plate glass negatives kept better than others. The trouble alluded to I have never seen on these plates.

Mr. MASON. Is there any peculiarity in the washing of your negatives?

Mr. GARDNER. I have been in the habit of using cyanide of potassium instead of hyposulphite. I do not clean with hyposulphite.

Mr. BOYLE. The statement made by Mr. Chapman, that plates coated with albumen were not so affected, implies that the albumen prevented the dampness of the atmosphere from acting upon the soda of the glass, and therefore saved the plates from that peculiar action.

## Talk in the Studio.

THE AMATEUR'S PHOTOGRAPHIC GUIDE BOOK.—Mr. W. J. Stillman has just issued a guide book for amateurs which will prove useful to many. Mr. Stillman is an indefatigable experimentalist, a skillful worker, and a careful observer. He has worked carefully with most of the dry processes, with emulsion processes he has experimented more than most men; and he describes operations clearly and accurately. With an unhesitating candour not often met with, he states his opinion

of various processes, and of various kinds of commercial plates; giving details on many points regarding which amateurs desire information not always attainable. Besides all this, the work contains concise simple instructions in the ordinary processes of photography, unencumbered with unnecessary matter. Altogether, the work will be at once welcome and useful to amateurs.

PICTORIAL BACKGROUNDS.—Mr. W. Tilley sends us some examples of cards with pictorial backgrounds produced by double printing, which is effected, he says, in a novel manner, more simple and easy than anything which has been described. Of the method we cannot, of course, speak, beyond saying that, judging from the results, it seems effective.

PRINTING FROM TWO NEGATIVES.—A correspondent signing "A Little Gun in the Provinces" sends us some examples of work which he has for some time been doing with two negatives for one print, the duplicate negative being produced by the wet process, the precise mode of producing it not being described. He sends in each case a print from the single negative, and one from the two negatives superposed. In the latter the results are in all cases greatly superior, having deeper, richer shadows; purer, brighter lights, with full half-tone and fine modelling; and that peculiar porcelain-like effect seen on "photo-mezzotints" produced by Carl Meinert's process. The results are encouraging, and with large heads, instead of full-length figures on cards, the pictures would be finer still. M. Denier's pictures produced in this way are large heads on cabinet plates.

CURIOS PHENOMENA.—Most photographers meet with curious and abnormal results occasionally, the record of which might be instructive, and would certainly be interesting. A correspondent of the *Philadelphia Photographer* says:—"A short time since I placed two ferrotype plates, in a wet state, face to face, and left them to dry. On taking them apart I found that the image on each plate had impressed itself on the other, just as perfectly as if it had been lighted and developed in the usual way. These plates had been just exposed, developed, cleaned, and washed in the usual way, and had dried during the night in the dark-room. I send you one of the plates." He adds: "Some years since I was copying a Daguerreotype, by the Daguerreotype process, and by oversight left the plate exposed to original all night, and until ten o'clock next day, when, on taking the plate out, I found a picture as distinctly formed as if it had been mercurialized; this to me was a puzzle, and is yet, as the copying-room was so far from the dark-room."

A SIMPLE WATER TANK.—A correspondent of our *Philadelphia contemporary* says:—"I will here describe how I make my photographic water-tanks. I have one I made six years ago last fall, after I had lost my gallery by fire, and not having left too much of the useful, I contrived in every way to be saving. I took some half-inch siding, planed the rough off, made a tank of it, got some white lead and oil and some cheap oil-cloth. I thinned the lead slightly with the oil, and painted the box inside with it as thick as I could brush it on; then pressed in the oil-cloth smooth all over, and tacked it around the top of the tank. Folded the oil-cloth in the corners so as to make it fit the tank. When putting the tank together I stay the joints with short pieces of wire, so that the oil-cloth won't break after the lead gets hard. This tank has been used almost daily ever since it was made, and it is good yet."

PHOTOGRAPHY IN VENICE.—Mr. E. L. Wilson, speaking of photography in Venice, says:—"Pictures for the camera bristle up about you in all directions, and really photography is one of the principal industries, for no one will leave Venice without a good supply. They are exceedingly well taken as a usual thing, and very cheap, of all sizes, from carte to full sheet. The largest producer is Signor Charles Naya, who has not only very fine salesrooms on St. Mark's Place, but a very extensive manufactory, so to speak, near the Grand Canal. We visited both, and found much to interest us. We noticed before, in many of the churches, a camera standing alone, exposed to some bit of carving, or sculpture, or painting. These were the servants of Signor Naya. He uses dry plates, and on such objects where the changes of light are not great, and where there is not much light at all, he often exposes as much as five days. Of course this cannot be done with exterior views. There are few photographic establishments in Europe more extensive than Signor Naya's. He occupies the whole of what was once an immense palace. His business is divided systematically into departments, in each of which is the usual number

of assistants. Madama Naya presides over all, and we found her most agreeable and intelligent. We were courteously shown the whole establishment, and all the operations, from the preparation of the plates to the printing and finishing. Fresh water is a scarce article in Venice, and is brought to the photographer daily. Washing the prints, therefore, must be done in the most economical manner—more economical, sad experience tells me, than effectual. I am sorry to say. Signor Naya produces some very pretty results by printing on blue paper, and then colouring the buildings, and putting in clouds. The results look like pictures elaborately coloured, but they are sold remarkably low. Signor Naya understands the policy of saving his wastes, and altogether his establishment is one of the best managed I ever saw throughout. I carried away a great weight of his pictures, and they refresh my memory of the lovely breathing time we had in 'Venice, my beautiful.'

**NOTE ON THE ACTION OF LIGHT UPON NITRIC ACID.**—By W. H. Aston Peake.—Pure nitric acid, when exposed to light for any length of time, gradually turns of a yellowish green tint, and the unoccupied portion of the bottle containing it becomes filled with brown fumes. On sealing a quantity of the acid in a flask, and exposing it to direct sunlight for three days, the action became very strongly marked, and on examination the acid was found to contain a considerable quantity of nitrous acid. I would presume, therefore, that the action is a reducing one.—*Chemical News.*

**DATES IN PORTRAITURE.**—The *Stationer* says that "in commemoration of Her Majesty's fifty-fourth birthday a photographer has published a photograph in cabinet and carte-de-visite sizes, in each of which is given two vignette portraits of the Queen, one representing her in 1840, and the other in 1874. Contrasts of portraiture of the same individuals are always interesting, but they have not in our opinion had sufficient attention paid to them. This publication may therefore prove the prelude to a new series."

## To Correspondents.

**FAIRPLAY** writes to point out that the explanation of the *soi-disant* "Henry Edward Thompson, M.D.," to the effect that his diploma "may be" American, will not hold water, inasmuch as whether it is English, American, or from any other source, the holder's name *must* be duly placed on the "Medical Register" before he can practise in this country. And he further points out that instead of producing any one who saw or heard of a collodio-chloride print before 1864, he quotes a passage from M. Gaudin which proves that his allusion four years earlier was an untested suggestion—so far untested, in fact, that he suggests the use of a chloride which is not soluble in collodion or in alcohol. We give the substance rather than the text of our correspondent's letter, because we do not wish to occupy more space with replies to vulgar abuse, nor to repeat refutations of statements which are not only unsupported by any evidence, but which practically refute themselves. The mythical "M.D." scarcely required any exposure; the trick was too transparent. The condition of mind which can take pleasure in such coarse antics is surely as worthy of pity as of grave castigation.

**T. W. REYNOLDS** writes to say that he fails in getting any approach to the rapidity often described with a variety of dry processes. Tannin, coffee, beer, albumen and coffee, and others, the exposure for which has been described as three times that of wet, he finds to give him poor results with ten times as long as wet, and he asks for aid in discovering the cause. He will see, on reflection, how impossible it is to give any definite aid upon such a general statement of experience. If he will describe in detail all the steps in any one of the processes in which he fails we may be able to suggest a source of error. He prefers the collodio-albumen process. If he succeeds with it he cannot do much better. With hot development, we have obtained good results with an exposure of three or four times wet collodion. With care, alkaline development may be successfully applied; but we prefer Mr. Mudd's method of using heat. The gum-gallic process succeeds well with three or four times wet exposure with the ordinary mode of development, and with the strong alkaline development it requires no more exposure than wet, as we have seen in Mr. Gordon's hands. The rapid albumen and coffee process gives, in M. Constant's hands, perfect as well as rapid results, which we have seen. Where our correspondent fails we cannot conjecture, except it be in slightly trying many processes instead of working out one with steady perseverance.

**T. Y. R.**—We cannot say with certainty what material will best answer to stop a leak in one of Doulton's glazed filters. Much depends upon the size and position of the crack. Marine glue is a favourite cement with us for such purposes. White lead may possibly answer. There are various cements sold for such purposes.

**B. L.**—What process do you use? How do you develop? In producing transparent positives on collodion, full exposure is of vital importance in obtaining a detailed, delicate image.

**NEWS AGENT.**—If the proper steps for securing a copyright in the picture were not taken at the time of producing and issuing it, no steps now taken will confer copyright. 2. No matter what the position of the sitter, if there be no copyright you can copy it; but equally, if the proper steps were taken, you cannot copy without infringing the law.

**R. A.**—Mr. Solomon used to keep the collodio-chloride paper prepared by Obernetter. We are uncertain whether he does so now or not. Mr. Bruce, of Dunse, obtains his, we believe, direct from Herr Obernetter in Munich. Messrs. Mawson and Swan supply collodio-chloride ready for use. Try Marion and Co. in regard to the punches for cutting medallions.

**D. E. D.**—We do not remember any one who undertakes the repair of rolling presses. Bury Brothers' firm no longer exists, we believe. Possibly the nature of the repair may permit it to be done by any working smith. We should not, in your position, hesitate, if other means fail, to consult Hughes and Kimber. If they do not undertake the work, they may tell you who will.

**DARTMOOR.**—Stereographs on glass are produced in many ways. Some are produced on wet plates, some on dry collodion plates, some on dry albumen, some by the Woodbury process. Those to which you refer as having the appearance of being inlaid on glass are probably printed with a protective mask which prevents the image being produced outside the mask.

**ELECTRO.**—The questions you ask could only be answered efficiently, we fear, by a manufacturer of electro-plate. The amount of silver by weight which should be deposited on a spoon or fork could only be determined, we apprehend, by a practical man; and so with your other questions. There are several manuals of electro-metallurgy published, from which you may derive some hints.

**CASTRO.**—If your collodion thickens by merely standing a week or two in bottle, it is manifestly not properly stopped, and the ether escapes. Use a good cork. If it thickens from use, dilute with new thin collodion. You may dilute with ether and alcohol; but unless these be pure, you may risk injuring the collodion.

**E. HEPTON.**—We have addressed and forwarded the letter. In making lime water you simply place a lump of quick-lime in a bottle of water, which will take up a minute trace of the lime, and no more.

**WARWICK BROOKES.**—The "Rembrandts" you forward have many fine qualities. The lighting is very effective, and the retouching managed with skill and delicacy, although, perhaps, a little in excess in some cases.

**CAPTAIN TURTON.**—We will write shortly.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PHOTOGRAPHY APPLIED TO MILITARY PURPOSES—PHOTOGRAPHS FOR THE MILLION—THE END OF A SAD STORY.

*Photography Applied to Military Purposes.*—A lecture has been delivered at Brussels upon the application of photography to military purposes, and the remarks made by the lecturer have since been printed for circulation among the Belgian soldiers, the pamphlet bearing the title of "Les Eléments de la Photographie." The author is Captain A. Hannot, who is appointed chief of the photographic establishment attached to the Belgian War Office, and is entrusted with the elaboration of the art in connection with military matters. In Paris, Captain Dumas has succeeded Commandant Lausselat, whose name was well known to photographers five years ago. Captain Dumas, who occupies a similar position in the French War Department, has also been very busy of late in making the best possible use of the camera in the War Office establishments, and has also suggested some useful applications of the art which would be, no doubt, capable of serviceable employment in war times. But the first comprehensive report on the subject of photography and war was a paper read in this country more than five years ago before the Royal United Service Institution by Mr. Baden Pritchard, of the War Department, Woolwich, in which he gave an account of the earliest applications of the art in the Crimean war, at the instigation of Lord Panmure, and showed how usefully the camera might be employed at the present day in making reconnaissances of an enemy's country, and also in securing sketches to accompany and illustrate military reports sent home. There can be no doubt that most important applications might be made of the camera in warfare, whether as a reconnoiterer or as a recorder of facts, although, possibly, the time is far distant when we shall accomplish what Chevalier was so sanguine of performing by means of his photographic plane-table, viz., that of directing the fire of a battery by night, or converging the firing of a number of guns upon one fixed point by the aid of data previously recorded in his instrument during the daytime.

*Photographs for the Million.*—Some little while ago we called attention to the issue of photo-mechanical prints in the London *Figaro*, and suggested that they were possibly produced at MM. Goupil et Cie's house in Paris. We have since been informed that they are printed in London at the Photo-Relief Printing Company's Works, Brompton. This first essay at producing cheap and permanent photographs with a twopenny journal seems to have been so successful that a penny publication is now to be issued which is also to be illustrated by a carte-de-visite portrait of some celebrity or other. One of the first portraits is to be that of the great Barium, whose picture many will be glad to possess, and one of Adeline Patti is to follow: "Patties a penny a piece" are cheap enough, in all conscience, and there can be no doubt as to such popular portraits as these finding a ready sale. Of course, with such a thriving trade in small pictures, other photographers must suffer, unless they also make a step of progress, for no one will give a shilling for what can be bought for a penny. It seems to us that the best thing would be for photographic publishers to inaugurate a size rather larger than the ordinary carte, and print as many vignettes as possible, for it is just this pleasing style that is the great stumbling block of mechanical processes. But unless something of this kind is done, the lucrative trade in photographic portraits must suffer considerably.

*The End of a Sad Story.*—The tragic end of a story which was last year mentioned in these columns was contained in the *Times* of Monday, under the heading of "Death on a Glacier." Our correspondent in August last,

writing from the Engadine, mentioned the case of an old gentleman in the hotel who was found missing one morning. Our correspondent, like most of the other residents, thought little about the matter, and the subject was looked upon in anything but a serious light for the first few days, for the gentleman in question was of eccentric habits, and had often disappeared for days together on some mountain excursion. In speaking of the company gossiping at table d'hôte, our correspondent said, "A matter has recently cropped up which excites the deep interest of us all. An old gentleman, who has been drinking the waters for some time past, has suddenly disappeared, and gone no one knows whither. We all suppose that something horrible has happened to him, because that, of course, makes his case all the more complicated and obscure. Every little fact relating to the missing one is thoroughly ventilated, and when he is under discussion we speak in hushed tones, and listen with bated breath. You would be sent to Coventry immediately if you suggested he had merely gone into Italy over the Bernina Pass, for that would, of course, be such a commonplace thing to do; and, besides, it would make an end to the mystery. He had a singular habit, had this old man, I am told, of asking everybody their name, and when his own was demanded he would refuse to give it. One day, however, it appears, on being pressed, he said his name was Brown. This was all very well, but, one fine day, another tourist named Brown made his appearance, and the latter straightway questioned the mysterious old man as to his right to the family appellation. Being thus brought to bay, the unknown then and there frankly acknowledged that his name was not Brown; but he never gave any other, so far as I can discover. The poor man's name, however (the Rev. Bertie Marriott), has now been found out, together with his remains, which have been lying upon the Morteratsch Glacier, unheeded, for nearly twelve months. He had wandered alone upon the dangerous ice fields, and slipped over some glassy precipice. It is singular that his body should have remained so long undiscovered, for guides and parties of excursionists do not unfrequently march over the ice in ascending some of the snowy peaks in the neighbourhood. Our correspondent himself was there on several occasions after the tragic event whilst engaged in securing camera pictures of the far-famed glacier.

### A PHOTOGRAPHIC ALBUM.

BY E. LEGOUVE.\*

PHOTOGRAPHY has a great fault; like all portrait painters, it often distorts the faces that it reproduces. I know of more than one photograph that is a calumny. First of all, there are faces that are anti-photographic—subjects whose likeness the sun never catches. Why? It might, perhaps, be possible to give more than one scientific reason, but the principal one is, that photography is employed to reproduce us only when we are at rest, condemned to immobility, and our features, consequently, are more or less disfigured by contraction.

It matters little that the reproduction of the features is exact. Our faces do not consist alone of the bony structure, but also of our physiognomy, of the movements of our hearts and minds, of that inside of which I have just spoken, and which acts on the outside when it causes our eyes to shine, our lips to palpitate, our nostrils to dilate, relieves the flesh from its materiality, and, finally, when it casts over our features the fire of anger, the radiance of joy, and the light of the mind or of the soul.

All these things go to make up our individuality. Now what becomes of them in photography? For example, what becomes of the man of imagination when the photographer hurls at his head his terrible—"Don't move! Don't move!" At this terrible phrase the features con-

\* Continued from page 315.

tract, the looks become troubled, the eyes water, the blood rushes to the heart and brain with violence; you are no longer yourself. We must, then, accept the photographic likeness only for what it is worth. It oftentimes deceives us by its strict exactness. For instance, I saw in this album the picture of an illustrious octogenarian of our day; this picture is a masterpiece, but one likely to deceive. This wrinkled forehead, these hollow cheeks, these sunken lips, these eyes nearly veiled by their lids, doubtless offer an admirable representation of the truth, but of a truth which is material and exterior, and which, consequently, is but one-half of the truth. To reproduce the age of the human face as we would that of a monument is to alter and to impair it. Those who have seen and heard this illustrious old man converse, know that, besides the him of this portrait there exists another he—one full of fire, of life, of grace, even, and from whose face, as if by enchantment, as soon as he speaks, fifteen or twenty years take their flight. Consequently, I have under my eyes but the half of the medal, and that the least exact half—the reverse side.

Photographic art abounds in errors of this kind. How can we correct these false impressions? How complete, at least partially, these insufficient testimonies? I know of one way of doing it. It would be necessary, in an album like this, to add to the picture of the personage a few lines of his writing. We are disposed to ridicule the persons who pretend to judge of one's character by his handwriting. This is an error. Writing is also a portrait, as are gait, actions, voice; as is everything that emanates from us. I am quite disinterested in speaking thus, as I write an abominable hand. Ah! I could explain to you, if I wished, in what and how this awful scrawl resembles me, but I prefer not to. It is certain that it would be very interesting to complete photography by autography. A simple phrase written by that illustrious old man at the bottom of his portrait would suffice to make us understand that the picture lies. The hand would protest against the face; and, thanks to that writing, so firm, so straight, so bold, suddenly from behind the impaired front of the temple would shine in our eyes the lamp of the sanctuary; that is to say, the eternal youth of the intelligence, of the character, and of the soul.

I offer my idea to the owners of albums. They will there find another means of indulging the ruling passion of our day, the most universal, the most common to all classes, to all ages, and to both sexes—curiosity! For, in speaking of curious persons, we always say—"Eve's daughters!" What about her sons?

I do not wish to close my remarks upon photographic art by a desideratum, when there are so many other merits pertaining to it of which I have not spoken. Ought I, for example, to omit mentioning it is a travelling companion? What a marvellous auxiliary in all great scientific expeditions. With what power it brings again before our eyes the gigantic monuments of the East, in all their striking originality. What a resurrection of nations long since passed away is this evocation of their temples, of their statues, of their gods, of their earth, of their sky—I am almost tempted to say, of their sun, for the depth of the shadows reveals the power of his light. And there is yet another blessing of photography which exceeds by far this one and all the others which I have mentioned.

Formerly, scientific inventions were too often curiosities of the laboratory, treasures of the sanctuary. To-day, the first condition of the conquests of genius is to resemble the sun, to shine for everyone. Photography has this glorious privilege: far from despising the common herd, it is for it that it was created.

It has placed within the reach of the most humble the great pleasure formerly reserved for the privileged classes—the pleasure of possessing the likenesses of those we love. Thanks to it, the poor peasant who leaves his

village for the army carries in his knapsack, not the baton of a marshal of France, but what is easier and not less pleasing, the portrait of his mother, with whom he has left his own.

Thanks to it, there is not an humble cot that may not hereafter possess, like the most aristocratic chateau, its gallery of family portraits—its collection of ancestors—for, be it said, we all have ancestors, and these genealogies of tradespeople, of artisans, of workmen, will not be less glorious nor less useful to their sons than they were for the descendants of the nobility, a long line of ambassadors, of generals, and of statesmen.

If the ones represent race, the others represent family; if the succession of brilliant uniforms, of dazzling decorations, kept up in the minds of the scions of nobility true sentiments of pride, the gradual changes from the blouse to the jacket, from the jacket to the coat, from the coat to the robe of the advocate or judge, will speak of courage and hope to the sons of the lower classes: the former learned from their fathers how not to fall, the latter will learn from theirs how to rise.

Have I said all? No; photography has this final claim to our gratitude.

What parents have not often made the sad reflection that, in reality, we lose our children every year? Even when God leaves them to us, time disputes our possession of them. Each day that passes takes away something belonging to them, even though it may render them more beautiful. The child of to-day is not like the child of yesterday, and, in its turn, will differ from the child of to-morrow. Years, in succeeding each other, devour each other; childhood absorbs infancy, only to disappear shortly in youth; so that when our daughter buds into womanhood, we have lost all that has preceded and produced this opening of the flower; we have lost the varying charms of her first fifteen years. Memory, however faithful it may be, possesses them but as a whole; the charming developments in their changes from day to day have escaped us. Well, photography repairs this cruel loss. It gives us back what time has stolen from us.

Let us, then, ask photography to give us each year pictures of our children, and forthwith we regain that series of metamorphoses through which they have passed. We find again together, with all their changes of face, all their transformations of intelligence or character; we feel, at the same time, reviving in our hearts all the joys, all the fears, all the hopes, that each of these transitions has given us. It is not they alone who live again before us, it is we who live again in our own eyes. And for whom? Still for them. Each one of these portraits is not only a joy, it is a lesson. Each one recalls to our mind a danger from which we have saved them, or a fault which we have combated in them. This review, which embraces all the career through which they have passed, teaches us to guide them in the career yet to follow, and, finally, if God afflicts us with the most terrible misfortune known to this sad earth: if we see die before us those who should have closed our eyes in death—then, at least, we shall have the consolation of preserving of them all that Providence has vouchsafed to us. Their future is taken from us, but their past belongs to us in its entirety.

## HOW TO MAKE A POCKET CAMERA.

BY W. J. LANCASTER.\*

WE must now turn our attention to the lenses used with these small cameras. We will suppose ourselves to possess a meniscus achromatic lens, having five inches focus from its back or convex surface; a series of brass tubes and castings; and a lathe, vice, and tools, for the purpose of making mount. The mount can be made either in a rigid form, or may be made with rack-work for adjustment; in

either case we must make a cell to hold lens. Supposing the lens to be  $1\frac{1}{2}$  in. diameter, then we must use a triple drawn piece of mandril tube, having an inside diameter of  $1\frac{3}{8}$  in., and outside diameter of  $1\frac{5}{8}$  in. The length should be about half an inch. This tube should be put upon a wooden chuck, and a space turned in just deep enough to allow the lens to be burnished in. The outside of the tube must be screwed, so as to enable one to screw it into the body of mount. The screw should be perfectly true with circumference of lens. The next part to make in a rigid mount is the body tube. This tube should be large enough to have cell screwed into it; it might be about  $1\frac{1}{2}$  in. inside diameter, strong mandril tube, having a length of in.; the cell containing lens to screw into back portion; the screw tools used should make a thread about 37 to the inch. The front part of body tube should also be screwed similar to the back part, for the purpose of taking a plate with hole in centre, and plate of revolving diaphragms on one side of the large plate. The diameter of this plate should be  $1\frac{1}{2}$  in.; it should have a projecting ring at the back, screwed with outside tool, having same thread as inside of front part of tube; also, a hole, half an inch diameter, should be turned in the centre of this plate; then a second circular plate, rotating on a screw, should be made  $1\frac{1}{2}$  in. in diameter, having four holes, varying from  $\frac{1}{2}$  in. to  $\frac{3}{8}$  in. They should be, respectively,  $\frac{1}{2}$  in.,  $\frac{3}{8}$  in.,  $\frac{1}{4}$  in., and  $\frac{3}{16}$  in., the amount of light entering through each being 1,  $\frac{1}{16}$ ,  $\frac{1}{4}$ ,  $\frac{1}{7}$ , thus giving an exposure exactly proportional to reduction of aperture, thus being in the proportion of 1, 2, 4, 7—that is, smallest diaphragm requires seven times the exposure of largest diaphragm, &c. The plate revolves on centre screw, and on its backed surface has small punched marks, which fit on to a pivot connected to a spring in inside of front part. The aperture in revolving diaphragms and front plate is closed by means of a moveable plate which should be  $\frac{1}{2}$  in. in width, so as to entirely cover the  $\frac{1}{2}$  in. aperture in front of mount; it is held down by a screw, on which it moves away from and over the aperture, a small pin preventing it going too far. If it is preferable to make a rackwork mount, then the tube containing cell with lens must have another tube outside, and sliding easily; on this outer tube is built the pinion rod, and strap holding pinion down, and a slit must be made in inner tube to hold a piece of rack same pitch as pinion; the screws in the strap holding pinion down regulate the pressure of pinion on rack. A milled head is turned to fit on end of pinion wire, for the purpose of focussing. A flange must now be made to hold lens on to camera; the large tube should be screwed outside and flange inside, so that lens may be taken off camera and carried separately. The arrangement of lenses for viewing image on ground glass, and dispensing with black cloth, consists of two plano-convex lenses mounted similar to a Coddington lens, with a diaphragm between them, the two plane surfaces being outside. The part nearest eye, when in use, should be very hollow, so that very little light can come to eye except from ground glass. The tube containing these lenses screws into another tube, blackened inside. In using the focussing lenses you hold tube against ground glass; screw in and out until you see the surface of the ground glass; then focus the image by turning pinion connected with achromatic lens.

The umbrella stand is made of six pieces of mandril tube the following lengths and diameters:—Obtain three pieces of best brass tubing about 28 in. long and  $\frac{1}{2}$  in. diameter outside measurement; then three pieces 29 in. long to fit easily into the first series; also three pieces to fit tight over small tubing, and to push tightly into large tubes. These should be 4 in. long, and are to be soldered over one end of small size tubes, thus allowing small tubes to be put into large tubes either way. A small ring is soldered around the middle of these short pieces of tube to prevent the tubes pushing too far into large tubes when stand is in use, and also when closed up. The tops of large tubes

have soldered into them a plug of metal, which is made into a joint by fitting into the casting which holds camera plate. This casting is about  $1\frac{1}{2}$  in. diameter, having a peg in centre to be screwed for holding camera, and three projections to fit into castings of tubes. The castings in tops of tubes are filed out, and the projection on top casting is ground into this space, into which it is fixed, when finished, by a pin or screw going through the whole. The bottoms of short tubes have a piece of metal soldered into them, and filed down to a point to stand in ground. A handle is made, and a piece of tubing flattened slightly on three sides to form the bottom, when packed, completes the whole. A cover can be made of silk or patent leather to suit the taste of the possessor.

#### PHOTOGRAPHING THE INTERIOR OF A WRECK.

THERE are few professions which more frequently call for ingenuity, and tax resource, than that of the photographer in general practice. He must be ready for any emergency, and be prepared to photograph everything possessing an objective existence which interests humanity. Mr. J. L. Gihon a while ago described, in our Philadelphia contemporary, a curious undertaking which may be interesting to our readers. The gentleman in question is engaged in photography in South America, and was called upon to photograph the interior of a vessel which had been found wrecked and deserted. He says:—

“When found drifting with the current along the coast, her interior was a mass of smouldering fire, but her hull, being of metal, merely glowed as only red-hot iron can. Speculation was rife as to what had become of the officers and crew, until they made their appearance in the city, after having trudged through many a weary league of sand. They told us of the fire which suddenly burst upon them, of their well-grounded fears of the explosion which they knew must follow (powder being aboard), of their abandonment of the vessel, of their precarious search for land, and of their after hardships. They were surprised to find that the remnants of their once beautiful craft had arrived in advance, and now began a disputation as to whom they should revert. Again, the underwriters in London had to be satisfied as to the condition of the wreck. A rational man suggested that as to the latter, a photograph of the interior would be the best report that could possibly be devised. Thus our connection with the affair commenced.

“I have worked under difficulties many a time, but have never yet encountered greater ones than this offered. The captain must have been a practical joker, for he assured me that I would suffer no inconvenience, that there was plenty of fresh water on board, and several state-rooms sufficiently dark for manipulation. As he professed to have been an amateur photographer, I had confidence in his statements, and, to my after disgust, abided by them.

“Starting off in one of the little sail boats that constantly hover about the moles, we soon get upon the bosom of the harbour, and as the wind freshens, ship just enough of the sea to completely drench all of the luggage. You know what the result will be—swelled apparatus, and chloride of silver wherever the nitrate has been. At last we reach the scared and disabled ship, and find no way of getting on board. A grapnel, however, skilfully thrown, attaches itself to the bulwarks, and gives us a chance to clamber up and over the sides, where we find no deck to stand upon. An immense shell filled with débris, with twisted beams, with immense links of chain, rusted anchors, broken machinery, sections of tubular masts, knotted coils of wire rope—all this, and more, similar in character—make up the scene we are to represent. Nothing daunted, ingenuity has to be taxed to get the traps on board, and to establish a place for them.

"It needs no scrutiny to establish the irony of the captain's remarks concerning the rooms. There remains to us the necessity for working, and there looms upon us the fact that there is no place for the purpose. Hesitation is useless, and as all that remains about us is of iron, we proceed to make use of it, and actually build a dark room, or rather kennel, out of great sheets, that have to be lugged from various parts of the piled up rubbish. Of course it is not light-tight, so we strip off coats and vests, and all that decency will allow, and cover over cracks, fill up corners, and succeed in having created a stinking, nasty, dirty hole, into which we have to crawl, and out of which we return thanks for the privilege of getting. And now for the water! To be sure, there is plenty around us, but it is as the old poem reminds us, "Water, water everywhere, but not a drop to drink," and, as we revise it, not a drop with which to wash. Diligent search, though, reveals the tops of iron tanks amidst the chaos, and in the bottoms of them we discover sufficient if we can get it. More impromptu mechanical devices come to our aid, and we finally commence work.

"It would be tedious to recapitulate the obstacles that obtrude themselves at every step, but they can be imagined when I explain that we were working 14x17 inch plates; that there was a heavy wind blowing; that the vessel itself had some motion; that there was no proper support for the camera; and that it would be impossible to suggest any one point that a photographer could look upon as conducive to either comfort or convenience. A successful negative ultimately crowning our efforts must be looked upon as the gaining of a genuine triumph."

#### OUT-DOOR PHOTOGRAPHY.

BY GEORGE WASHINGTON WILSON.

[MR. WILSON has prepared for American circulation a little work entitled *Wilson's Landscape Studies*, from which the following is an extract.]

My success is due to care, and I have used the following formula for ten years:—

*Bath.*—Ordinary 30-grain bath of nitrate of silver, without anything added to it, except about four grains of iodide of potassium to every sixteen ounces.

*Collodion.*—As I never could make it to please myself, I always buy it from some respectable maker.

*Glass.*—In the long run it is cheaper to have first quality glass, and I pay something extra to have it packed with a piece of paper between each plate, to prevent the surfaces being scratched during transit.

*Developer.*—Glacial acetic acid ... .. 1 ounce  
Water ... .. 16 ounces  
Protosulphate of iron 15 to 30 grains  
to the ounce of solution.

The proportions require to be varied so much according to circumstances, that it is impossible to give them exact. With a little practice, one soon learns to regulate the strength of the iron and acid to suit the work in hand. In warm weather I dilute the developer immediately before using it; consequently can carry in one bottle as much as, when diluted, would make two.

*Lenses.*—I use, for full-sized plates, a triplet of about 8-inch focus, a pair of view lenses, single meniscus, 8-inch focus, one pair 6-inch, one pair 4½-inch, one pair doublets 3½-inch, and one pair doublets 2½-inch.

*Exposure, &c.*—If it is a subject we are attempting which can be taken instantaneously, I use my six-inch focus lenses with a five-eighth inch stop, and expose by removing and replacing the cap of the lens as quickly as possible; but if it is a subject requiring a long exposure, I make a guess for the first plate, and, from long habit, generally succeed in hitting it pretty exactly.

Some days, when, owing to the variation of the intensity of the light on the amount of shadow in the views, I have begun in the morning with an exposure of ten seconds, I have ended in the afternoon with one of three minutes, without losing a plate from either over or under exposure during the day. In spring the actinic property of light appears to be very active, and it is only then that I have succeeded in getting passable instantaneous pictures. Early in the season, views of buildings may be taken with a small stop, in from two to ten seconds, and landscapes, with trees, in from five to fifteen seconds; but by the month of August and September I find from thirty to sixty-six seconds are required for most landscape views, and instantaneous exposures are of no use except for clouds and water only.

The plate being exposed, I get myself shut up in the tent, and develop in the usual way by dashing on the solution as quickly as possible, and moving about the plate to prevent stains. If it is an instantaneous view, all the details should come up slowly and distinctly; but I keep on moving the plate for two or three minutes so as to get all that I can up before washing off the developer. This I do carefully and slowly, and as the negative, in this stage, is very thin in deposit, I pour from my dropping bottle a small stream of nitrate of silver along the side of the plate, and let it flow over the whole surface, before dashing on a fresh dose of developing solution, keeping the plate moving as usual. When this has acted for a minute or so, I wash it off again very carefully, and repeat the process—sometimes three or four times if necessary—until the requisite printing density is attained; then, after a slight washing, I bring it outside the tent, wash thoroughly, and fix with cyanide of potassium. If the plate has had a long exposure, with a small stop, I find one redevelopment generally enough; but if my plate looks too thin after fixing, I sometimes take it into the tent and redevelop a second time. The cyanide, however, must be well washed off, otherwise there is danger of getting a reddish deposit upon the shadows.

*Printing.*—I am not aware that there is anything peculiar in my printing operations, but I may mention that I use what some people consider a weak bath: twenty-five to thirty-five grains of nitrate of silver to the ounce of water, and the solution made neutral with a few drops of ammonia. After the prints are fixed in hyposulphite of soda, they are put up in bundles of about fifty, and subjected to the pressure of a machine, acting on the principle of a screw-press, which squeezes most of the liquid out of them. They are then washed by throwing them separately from one dish of clean water into another several times, and again subjected to pressure; and I believe that, after a few repetitions of this process, they are as free from hyposulphite of soda as it is possible for prints to be; but I generally allow them to swell in porcelain dishes, with siphons, which empty and fill mechanically all night.

#### ON DUPLEX IMAGES.

BY W. H. WARNER.\*

The negative now brought to your notice is that of the parish church of Denbigh, North Wales, called "Eglwys Wen," or "White Church," in which the two east windows face you as you enter, the western wall at your back being very uneven as regards surface, and of a dirty yellow colour.

On placing the camera in position no image was observable; yet, on completion of exposure—twice, on two separate occasions—the two east windows, the one plainer than the other, appeared in an inverted form as floating in the air between the pews and the camera. At length, on a third trial, a picture was obtained without it.

\* A communication to the Liverpool Amateur Photographic Association.

And now to describe the conditions under which the first two were taken, of which one negative is before you.

First, as to the light. The time selected was from ten to twelve on a dull day. After the strong light had ceased to pour in from the eastern windows—and the side light was stronger than the front, in order the better to ensure the having of only the light from the object itself—the camera was placed *behind* the half open door. A five and a quarter inch wide-angle rectilinear lens by Dallmeyer, with open aperture, was used on the occasion. The exposure, in the two first instances, was 105 minutes, the windows on the south of the church being old and yellow. You will see the result.

The perfect negative was obtained under slightly different conditions. The time selected was a bright afternoon from two to four, the sun being then more westerly, leaving the east end in a comparatively dull light. The door of the church was placed wide open, and the camera, with a five and a-quarter single wide-angle landscape lens, by Dallmeyer, with a nine by seven plate, was exposed forty-five minutes, standing in the diffused light. No spirit image appeared. The negative was clean, and free from stains. Half-an-hour after this development, when the bright light in the south-west had subsided, and the eastern sky, from refraction from the western, was brightening, the inverted image of the window was seen making its appearance in the old place, and, on closing the door of the church, it became stronger. I can only account for it thus:—That the western wall at my back acted in the same way as a pad of red blotting-paper at the back of a sensitised plate, the air between it and the pews being a focussing-screen; that when the direct light was greater than the diffused, the image appeared, and *vice versa*. The church is a very cold and damp one, being thus favourable to such a state of things, and conducting highly to the sensitiveness of the plate, that of forty-five minutes' exposure not being stained in the least. Damp atmospheres have, I think, an inducement to such appearances.

After a storm of rain, in photographing the north transept of Tintern Abbey, I obtained the mullions of a window situate high up in the gable, and also the five mullions of the western window, both being reflected apparently on the ground a short distance in front of the subjects. The latter picture was largely bought by an American medium to support his theory of the spirits of nuns appearing in the Holy Abbey. Opposite to each of these windows was a mass of air, with trees and cliffs at the immediate background, similar, as regards photo-colour, to that of the western wall of the church.

### PHOTO BLOCK PRINTING

BY WALTER WOODBURY.

THE following invention was only provisionally specified. It consists in an application of the photo-relief process to the production of blocks for surface-printing. It is as follows:—

“Firstly. To a method of obtaining by photography blocks suitable for employing with type, in the ordinary method of typographic printing, either from a subject represented by lines as an engraving or wood-cut, or from a photograph containing only half-tones, as a portrait or landscape from nature or a painting.

“Secondly, to improvements in the process known and termed in the trade ‘Woodburytype,’ by which that process is rendered much simpler.

“Thirdly, to an improved method of producing the same by machinery.

“To accomplish the first part of my invention I proceed as

follows:—Where the subject is in line I make a positive photograph of it (*i. e.*, positive by transmitted light), and from this I obtain a relief in gelatine by the ordinary method, the result being that the hollows of the relief will all be of one uniform depth, this characteristic producing a level or uniform surface in the resulting mould, which I make by impressing this relief into metal by hydraulic or other pressure, or by the method stated in the second part of this invention. Where the subject is in half-tone, as in a photograph from nature, I proceed as follows:—In printing on the gelatine film I interpose between it and the negative a photograph, on mica or transparent collodion, of what is known as mosquito netting, or Brussels net, which breaks up the resulting relief into a multitude of five square or hexagonal lines. To obtain from this a printing block I employ the means already described, the resulting block in soft metal being capable of giving from one hundred to two hundred impressions; but where large numbers are wanted, I electrotype this block in the ordinary way. I use diffused light to produce the block from half-tone negatives, as in that case the light in the parts that represent the whites creeps around the lines, thus obliterating them in that part, and leaving them strongest only in the parts printing dark. I sometimes adopt another method. I take a negative of the network by transmitted light, and copy this together with the negative, thus producing a positive with the lines already thereon, from which I proceed to make a relief as stated.

“To accomplish the second part of my invention I proceed as follows:—In place of using a thin film of collodion (as is generally used in the process called ‘Woodburytype’) to hold the gelatine of the relief, I proceed as follows:—I first rub over a sheet of plate glass with French chalk or ox-gall, and then coat with the bichromatized gelatine solution as now used. When this is dried and ready for use, I expose the side that was next to the glass for a few seconds to daylight before exposing it under the negative. This has the effect of causing a thin film of the gelatine to become insoluble, which, after subsequent exposure under the negative, will not wash away, but form a support for the photographic image afterwards impressed, thus doing away with the expense and trouble of the double coatings as now practised. When the gelatine relief is dried in the ordinary way, I take a thin sheet of tinfoil (same size as the gelatine relief), and attach it by gum or other adhesive substance around the edges to the gelatine relief. I now lay on the back of this a stout sheet of plate paper, and pass the whole through an ordinary rolling press; the tinfoil is by this means impressed into all the details of the relief; but in that state it would be useless to print from. I then proceed as follows:—A shallow metal box is filled with a composition of shellac and asphalt, which, on warming, becomes soft, but hardens on cooling. This box is placed on a hot plate until the composition it contains softens; it is then placed on the lower plate of the ordinary Woodbury printing-press, the foil and relief laid on it, the press closed, and the pressure applied by the under screw. When the composition has hardened, the tinfoil adheres to it, and I remove the gelatine relief from the foil, and use the foil-backed mould to print from. In place of fixing the proofs by alum or other substance of a like nature, I varnish the proofs with an ordinary varnish composed of shellac and alcohol, which gives the print the effect of a photograph on albumenized paper, at the same time protecting the surface from moisture. I also sometimes use the composition melted in boxes without the foil as a printing mould direct, and when sufficient numbers have been printed the box holding the composition is again heated, and can be used over and over again.

“The third part of my invention consists in an improved method of printing ‘Woodburytype’ by machinery. This I accomplish as follows:—Out of a solid block of iron I have turned a cylindrical hole in which is made to fit very loosely a cylinder of soft metal having a taper or conical hole through it lengthwise. Between the interior of the steel block and the soft metal cylinder I insert the gelatine reliefs, then by means of a taper or wedge-shaped spindle (roughened) I drive, by hammering or by pressure, the soft metal against the iron cylinder, thus impressing the relief on the outside of the metal cylinder, the taper spindle at the same time forming a shaft for the cylinder to be used in the process of printing. I then mount this roller bearing the relief in vertical slots in a frame having a bed of plate glass on which the paper rests, the roller resting on the glass by its own weight, and being dragged round by the paper itself; or in place of the glass plate I allow the soft metal cylinder to lie on another fixed or movable roller of metal or glass. The latter may be hollow, so as to reduce its temperature in hot weather by a stream of cold water running through it.”

## THE HEALTH OF PHOTOGRAPHERS.

EVERY practical photographer will read the articles of Dr. Napias upon the practice of photography in its relation to health, the conclusion of which we publish this week, with deep interest. "There is nothing in the photographer's calling," he observes, "really injurious to health or life." The valetudinary photographer who suffers from headache, depression, irregular appetite, and general debility, and feels disposed to charge these and many other uncomfortable symptoms to the hot and close atmosphere, in which he spends many hours daily, and to the chemicals he breathes or absorbs, will read with satisfaction this dictum of a medical man who has for some time made a special study of the health of photographers. Possibly, in some cases, a little scepticism will be mingled with the satisfaction; for whilst the practice of photography need not be unhealthy, there cannot be a doubt that it is often conducted under conditions that are very trying to many constitutions. The operator who passes many hours daily in the tropical temperature of a glass room; or in the dark-room, often unventilated, reeking with the mingled fumes of ether, alcohol, acetic acid, cyanide, decomposing hyposulphite, and often a variety of other chemicals, the debris of experimental work, unnecessary, unused, but stored on the dark-room shelves, is unquestionably subject to conditions more detrimental to health than those whose duties permit them to breathe fresh air whilst earning their daily bread. There are other conditions in the working photographer's life which are at times detrimental to the maintenance of sound health. Dr. Napias, indeed, admits these conditions in pointing out the best remedies for the disabilities to which the photographer is subject in breathing the ether-laden atmosphere of the dark-room, and for the gradual absorption or accidental swallowing of the poisons with which he works. In calling attention to these articles, we wish briefly to supplement some of the suggestions they contain.

There are two conditions of health of the most vital importance, which are, unfortunately, most constantly overlooked or neglected, and to which Dr. Napias has scarcely referred in his articles; we refer to ventilation and regularity in diet. The glass-room itself is often very insufficiently ventilated, and its heat is oppressive to the sitter who visits it for even a quarter of an hour. But it is to the ventilation of the dark-room we especially refer, which is too often of the most imperfect and inoperative character. The ordinary means of ventilation secured by opening windows are, of course, not available during the many hours in which the operator in a busy establishment is engaged therein; and as special means are often

neglected, the majority of dark-rooms are offensive and unwholesome in greater or less degree. Special appliances are necessary to keep a dark-room well ventilated; but these, various in kind, are generally simple and easy to apply. As air will travel in any direction, and round any number of corners, and light only travels in straight lines, it is not difficult to admit air without admitting light, and we need not discuss the various mechanical appliances for effecting the purpose here. One thing only it may be needful to recall to the minds of photographers here: the vapours of ether, which are generally most prevalent in the dark-room, and have the most potent effect on the nervous system, are heavier than the atmosphere, and fall downwards; hence, to get effectually rid of them, there should be some aperture or apertures to permit them to pass out at the floor. If a good current of fresh air can be arranged to enter the room near the operator's face, and pass out near his feet, the most perfect and wholesome ventilation will be secured. Such ventilation is of vital importance to health; and by securing health and comfort it aids in securing more perfect results. If the dark-room be large and well lighted, and if all unnecessary bottles, vessels, chemicals, and rubbish be carefully banished from it, both comfort and health will be further secured. It is scarcely necessary to add, that an hour's brisk walk in the fresh air after a few hours in the dark-room will ventilate the photographer's clothing, and ventilate and purify his lungs most beneficially.

Another point very difficult to deal with is the question of taking food during the busy hours of daylight. Many photographers who are masters of themselves, and owe obedience to no law but that of making hay whilst the sun shines, neglect to take food during the busy bright hours, from nine in the morning until five or six in the evening. In some houses there is no definite provision for assistants taking a mid-day meal. This long fasting, or uncertain and irregular opportunities of eating, whether voluntarily undertaken or at the command of an employer, is unquestionably, in many cases, most injurious. A person of vigorous constitution and healthy habits may fast eight hours without discomfort or injury; but to the person of feeble constitution, and of the dyspeptic tendency which is frequently the result of sedentary and absorbing occupation, regularity in taking food at moderate intervals is imperative to health. Long fasting in a vitiated atmosphere, engaged in an occupation which keeps the nervous system at full tension, produces exhaustion, and incapacity for taking simple, wholesome food, and incapacity for digesting the food when taken; and also produces at the same time a desire for some kind of stimulant which shall temporarily revive the jaded system; and this mode of life persisted in generally brings, sooner or later, broken health. We strongly commend all photographers who are themselves masters of their time to secure at least half an hour, or more if possible, for rest and food about one o'clock every day; and we strongly urge employers who do not already concede a period for dinner to afford a like time to all in their employment. In some large establishments we know this is already done; but in others we know the time for mid-day refreshment is furtively snatched, such cessation from mid-day work not being recognized by the principals. Even where a number of young ladies are employed, less able than men to bear the prolonged fast, we have heard of cases where a surreptitiously eaten bun or sandwich was the only substitute for dinner they could obtain between nine in the morning and six in the evening.

We shall add no comment upon the admirable summary of the toxic effects of various chemicals found in daily use by the photographer, and the remedies Dr. Napias suggests for their effects, either absorbed by the skin or the lungs, or swallowed, beyond once more urging photographers to banish the dangerous cyanide from their premises.

REPRODUCING NEGATIVES BY THE POWDER PROCESS.

A FEW more suggestions, chiefly based upon the practical demonstration recently given by Mr. Wratten at the South London Society, may be interesting to many of our readers. A point of considerable importance, materially influencing not merely comfort, but success, in working, is an operating room free from draughts, and with a moderately dry atmosphere. The very quality upon which the process is based consists in the sensitively hygrometric condition of the film upon which the image is produced. A draught of damp air passing over the plate will materially modify, at once, those conditions which the operator should have strictly under his control. The room being free from draughts, and not too damp, the operator can at will modify the condition of the film, by very gently blowing upon it; but unless the atmosphere be very dry, and the film insufficiently adhesive to hold the powdered graphite, this will rarely be required.

The syrupy film, it should be borne in mind, must be quite dry before it is exposed under the negative. The contrivance used by Mr. Wratten to secure even drying was very useful, and the best plan we know of drying a plate in the absence of a bright fire. It consists of a tin vessel, something like a dipping bath, which is filled with water, placed on a stand at a slight inclination, and the flame of a spirit lamp placed, underneath it to heat the water. The plate is laid on the flat side, resting on a ledge, and is thus warmed evenly all over, without the risk of cracking, which the direct application of a flame to the back of the plate inevitably involves. Experience will soon enable the operator to determine when the plate is ready for exposure under the negative; of course, anything like moisture or tackiness must be removed, or the film might adhere to the negative; but when dry it may with advantage be exposed under the negative whilst still warm.

The exposure must depend, of course, on the density of the negative and the strength of the light. Those who possess a magnesium lamp will find a great advantage in its use, as affording a light of constant intensity; the number of feet of the wire found necessary for one experiment serving, within the varying limits determined by varying intensities, for all. Mr. Wratten used at the South London demonstration three feet of wire, about equivalent, as he estimated, to five minutes of diffused daylight. By under-exposure, an image is obtained which too readily takes the powder, burying the detail in the shadows, and which when printed would yield a flat white image. Over-exposure also yields a flat negative, giving a print with excess of shadow. A pale brown visible image is formed on the film, in which, when opal glass is used for supporting the film, the picture in full detail may be clearly seen. The advantage of opal glass is found in developing the image by means of the powdered plumbago, the progress of the work being much better seen on the white surface. Some difficulty was mentioned, at the South London meeting, in obtaining opal glass sufficiently flat to be used for printing without loss of sharpness and without risk to the negative. The glass known as "patent plate" opal is free from all objection of this kind.

The development of the image by applying the powder is an operation requiring care, patience, judgment, and delicacy of touch. The plumbago should be ground especially fine, and sifted, to remove any trace of grit or coarse particles. Mr. Wratten stated that his was that which is prepared for use in electrotyping, in the state of an absolutely impalpable powder. Mr. Howard had succeeded with the lead removed from a lead pencil thoroughly pounded in a mortar. A large camel's hair brush is used for applying the powder, which is done by gently rubbing it on the surface. If a drag of the brush is felt against the surface, there is too much moisture in the atmosphere; or it may be that the plate has been

insufficiently exposed. If it be from excess of moisture in the atmosphere, the plate may be dried again with gentle heat. If the plumbago does not adhere sufficiently readily, gently blowing on the plate may improve the conditions. Steady application of the powder, gently and patiently, sometimes for five or ten minutes, will gradually bring up the image to the required intensity.

Various formula for hygrometric mixture have been published and advocated. In the earliest formula of the kind, that used by MM. Salmon and Garnier in a powder carbon process, a solution of white sugar, albumen, and bichromate of ammonia was used. Joubert, in his enamel process, used a similar preparation, substituting honey for sugar. In Leth's enamelling process a solution of gum-arabic, honey, and bichromate were employed. Herr Obernetter and Mr. Woodbury each use a different solution, formulæ of which we have recently published. Mr. Wratten's preparation appeared to answer admirably. We repeat details, to facilitate reference, here:—

Dextrine	...	...	...	...	$\frac{1}{2}$	ounce
Grape sugar	...	...	...	...	$\frac{1}{2}$	"
Bichromate of ammonia	...	...	...	...	$\frac{1}{2}$	"
Water	...	...	...	...	10	ounces.

Almost any salt of chromic acid, or chromic acid itself, may be employed for rendering the syrup sensitive. Bichromate of ammonia possesses advantages in ready solubility, and in conferring the greatest sensitiveness; but as it is much dearer than bichromate of potash, many photographers prefer the latter. Bichromate of potash is soluble in ten parts of water; bichromate of ammonia in four parts of water. A neutral chromate, which we recommended in our work on pigment printing half-a-dozen years ago, is very convenient; it is formed by neutralizing a saturated solution of bichromate of potash with liquid ammonia.

The transfer of the film is a comparatively easy matter. Where a reversed negative is required, as in some of the carbon and mechanical printing processes, transfer is not absolutely necessary, and the negative may be finished on glass upon which it has been produced by simply washing to remove the bichromate, and varnishing. But even in such cases transfer is, we think, wise; and if the plate be coated with collodion first, and again with collodion after development, it may be preserved in this way, and used on either side, without transferring to a glass support. The completely developed negative is coated with a tough plain collodion, and placed in a dish of water, which serves the double purpose of washing away the unchanged bichromate, and loosening the film. Should the collodion employed be of a somewhat adherent nature, a few drops of sulphuric acid, or a few grains of citric acid added to the water, will aid the loosening of the film, which, by neat manipulation, may be transferred from the water to some flat surface to dry, or to another glass if it be intended to use glass again for its support. In the latter case, where the negative is to be reversed, it is found to adhere better to the fresh plate if it be floated for a few moments on a fifty-grain solution of sugar.

Besides the mere duplication of negatives, this process has many applications. As Mr. Woodbury pointed out in a recent article, it is valuable as a special means of strengthening ordinary negatives. As we pointed out, it is the simplest method of producing duplicate negatives of special character for printing from two negatives at once; or, as in Mr. Edward's practice, it may be used to repeat the negative at the back of the original image. As a means of producing enlarged negatives direct, without the intervention of a transparency, it is clear it may be found very useful, fifteen minutes of ordinary daylight having been found in Mr. Wratten's experience sufficient exposure in such case. For reproducing transparencies it offers many advantages, and leaves the tone or colour almost entirely in the operator's hands. What other application it may have remains to be seen.

## FRENCH CORRESPONDENCE.

THE FRENCH PHOTOGRAPHIC SOCIETY—REMOVING VARNISH AND NEGATIVE FILMS—ACTION OF LIGHT ON BICHROMATED GELATINE—SCIENTIFIC PHOTOGRAPHY—PHOTOGRAPHIC SANITATION.

THE French Photographic Society held a meeting on the 3rd July, but the heat was so great, and the attendance of members so scanty, that it was decided to adjourn, after a little while, over the usual vacation. The rooms of the society are, unfortunately, ill-suited to its requirements, and it is of urgent necessity that some alterations be made forthwith. The report of the jury of the exhibition was read; and while on this subject I would crave permission to reply in a few words to the letter signed "N." which appeared in the last number of the PHOTOGRAPHIC NEWS. Your esteemed correspondent reproaches me for having expressed too much satisfaction upon the liberal distribution of medals made to exhibitors. I think that if he had paid a visit to the exhibition in question he would have shared my opinion upon the great value of most of the works there collected together. In according seventy-four awards to the eighty-four exhibitors the jury had even to express their regret in having to exclude ten from sharing the honours. A critic cannot do less than bear testimony to the zeal with which everybody has worked to achieve success, and I do not see that the unusually large number of works of value can in any way depreciate their respective merits. All the better for the exhibitors and for the photographic art, for the works are homage paid to the great cause of progress. I will here repeat what I have said on the subject elsewhere: when, in time of war, a regiment especially distinguishes itself, it is honoured and "decorated," as a whole, by attaching to its flag the cross of honour, so that injustice may be done to no one.

Among the few communications made on Friday last to the society there was one of great practical interest, and easy of appreciation. It was a process for removing the varnish and the negative film from glass plates, and was described by M. Rousselon, who has employed it successfully for a long time. He dissolves eight grammes of caustic potash and four decigrammes of carbonate of potash in one hundred and seventy cubic centimetres of distilled water, and pours into this solution five hundred cubic centimetres of alcohol at 40°. Lac varnish is removed with ease by means of this liquid, Sœhnée varnish and some other special ones requiring a little more potash. When the cliché has been totally denuded of varnish, it is washed, and plunged at once into a bath of distilled water containing about two per cent. of hydrochloric acid, the plate being withdrawn as soon as one or other of the corners shows signs of rising, and is then placed to drain. As soon as the cliché is perfectly dry it is placed in contact with steam until entirely covered with drops of condensed moisture, and then there is poured upon it a slight film of the following preparation:—One hundred grammes of gelatine are dissolved in seven hundred grammes of distilled water, and to this are added (in summer) nineteen grammes of glycerine, and in winter rather less. As soon as the materials are thoroughly dissolved, ten cubic centimetres of a ten per cent. solution of chrome alum for every hundred grammes of gelatine are added. The cliché is then allowed to dry completely, after which it is covered with normal collodion prepared with castor oil. The film is again dried, and then the margins are cut with a pen-knife, and the pellicle removed from the glass.

M. Gobert, who has just returned from England, gave some account of a visit he paid to the photographic studios at the Arsenal at Woolwich, in charge of Mr. Baden Pritchard, and exhibited to the members of the society, by whom they were much admired, several carbon prints produced in these departments. In regard to these pictures, the discussion was revived, which took place some

months ago, relative to the continued action of the light upon a bichromated gelatine film after this has once been exposed to the action of the solar rays. Many gentlemen in this country, especially MM. Rousselon, Andra, and Gobert, have experimented in the matter, but without securing the results claimed by English experimenters. As it never entered our minds, in this country, to doubt the statements made by MM. Abney, Baden Pritchard, and others, it is believed that the conditions under which these gentlemen operate differ materially from those of French operators. It would be interesting to know something more of the matter, and I would ask one of these gentlemen to be good enough to favour me with a communication on the subject for insertion in the *Moniteur de la Photographie*, so that the question may be fully discussed.

M. Janssen, who has been charged by the Academy of Sciences to direct the expedition to Japan to observe the approaching transit of Venus, has not been simply content with one of the apparatus supplied by the Official Commission to all officers sent out by them to different parts of the globe, but has constructed, besides, a special instrument which will permit him to obtain photographs similar to those secured by observers of other nations, who have all adopted a system to obtain large images. This apparatus, of which every part has been scientifically considered, and with the greatest care, has an aperture of five inches, and a focus of two metres. It gives very clear images, of which M. Janssen has presented several specimens to the Academy at its last sitting, where they were greatly admired. On this occasion M. Janssen pointed out the important service that photography can render to astronomy; and among other things he stated that the daily depiction of the sun's disc was of considerable value, as showing the changes undergone by the orb which carries within it the physical secrets of our own system. M. Janssen is so convinced of the valuable aid which photography may render to the science of photography, that he regrets sincerely to see the applications of the new art so much neglected in France. We are, in fact, behind other nations in this respect, although, in 1858, M. Faye presented to the Academy a fine picture of the eclipse of the sun that took place on the 19th March of that year, and which, at the time, caused a great sensation in the scientific world. But it is foreign nations who have profited by the example of our countrymen. The works of Dr. Warren de la Rue are too well known by the readers of this journal to render it necessary for me to refer to them here; and as to those of Mr. Rutherford, of New York, they prove that in America scientific photography is not forgotten. In Germany, in Russia, and in Italy, astronomical photography has also made progress. Let us hope that, thanks to the efforts of MM. Faye and Janssen, and of those gentlemen aiding in the observations of the transit of Venus, the study of this branch of photography in France will receive fresh impetus.

English photographers have doubtless not yet forgotten the name of Camille Silvy, who, having practised photography in France with great success as an amateur, founded some time ago in London a photographic studio, which became one of the most important in the metropolis. Now I have just received from M. Silvy a letter which proves amply the public utility of the paper recently published by Dr. Henri Napias upon "Photography from a Sanitary Point of View." M. Silvy tells me that "he was, and is still, the victim of cyanide of potassium." He employed the compound in immoderate quantities to wash his hands and arms for several years; he has even swallowed little doses of it, involuntarily—when, for instance, he has touched food and fruit with his hands previously soiled with cyanide. If I do not mistake, it is more than four years since M. Silvy gave up photography, and yet he is to this day under treatment from the effects of this dangerous compound. This is a sad example to

add to the many cases of the kind which have already come under my observation. I cannot urge photographers too much to read carefully Dr. Napias's paper, and to follow the advice he gives for preventing and remedying accidents, and to bear in mind his clear and precise prescriptions.

ERNEST LACAN.

### SUGGESTIONS FOR RAISING THE STATUS OF PHOTOGRAPHY GENERALLY THROUGHOUT THE UNITED KINGDOM.

BY GEORGE HOOPER.

I BEG to submit the following brief suggestions to all interested in our art, as means whereby the status of photography may be raised in public estimation, and new interest given to the practice of the art, alike to amateur and professional photographers. My remarks merely contain the skeleton of a plan, but they may possibly be sufficiently suggestive to induce practical men to aid in giving the dry bones vitality and usefulness.

During the term of the forthcoming exhibition, let a special conference of photographers be held to decide upon the best means to be used to further the above object.

The executive of all the provincial societies shall be invited to meet the council of the Photographic Society of Great Britain, to discuss the following points, and frame resolutions to be passed at the above conference.

1. That for the general advancement of the art, it is desirable to secure the united action of all the societies in the kingdom, and that the Photographic Society of Great Britain shall be considered the central society, from which all such united action must emanate.

2. That all the societies in the kingdom shall arrange to hold their eight monthly meetings during the same eight months of the year: that all the provincial societies' meetings shall be held during the first week of such eight months, and those of the central society, as usual, on the second Tuesday of such eight months.

3. That the transactions of all the societies shall be published in the Journal of the Photographic Society of Great Britain, and that this journal shall be considered as the official organ of all the societies in the kingdom. A copy of same shall be sent to every member free, each society contributing its portion towards the extra expense so incurred.

4. That an exhibition of the progress of the art shall be held every year, but not necessarily in London. That it shall be opened by a soirée, and, if possible, some royal or distinguished personage shall be present.

5. That, if practicable, the next annual exhibition shall be held at Edinburgh, and the executive of the Edinburgh Society and that of the Central Society shall unite in forming a deputation to request the Lord Provost of Edinburgh to open same, and shall further use every means to obtain, if possible, a visit by Her Majesty the Queen.

6. Admission shall be charged to all non-members of societies, and every exhibition made self-supporting.

7. That a conference of photographers be held annually, during the month and in the town selected for the exhibition, such conference to last one, two, or three days, according to arrangements with the general executive.

8. A medal shall be awarded for any new discovery in connection with the art.

9. Any complaints shall be sent in to the general executive, and disputes submitted and settled by arbitration.

10. Any surplus funds from exhibitions or general contributions shall be placed in the hands of the treasurer of the general executive.

### PHOTOGRAPHY FROM A SANITARY POINT OF VIEW.

BY DR. H. NAPIAS.\*

*Nitrate of Silver.*—Nitrate of silver, so constantly employed in photography, is a violent caustic, the employment of which is not unattended by danger. Its local external action is generally confined to the production upon the skin of brown patches which speedily become black. These spots disappear at the end of some days by abrasion of the cuticle, but they may be artificially removed by repeated washing in dilute nitric acid or iodide of potassium. These are methods which take time, and only partially succeed, but cyanide of potassium, on the other hand, very quickly removes the marks. The employment of cyanide, however, although the most effective plan of getting rid of the black stains, is attended by grave dangers, and we need not repeat what we have previously said on the subject. Taken internally, nitrate of silver is an irritant and very energetic poison. This fact deserves to be known, although cases of poisoning by its means are rare, the best antidote that can be employed under the circumstances being common salt or chloride of sodium. A glass of water containing a good pinch of salt, or a cup of broth highly salted, contributes much to allay the injurious effects of this dangerous poison.

*Bichromate of Potash.*—This salt, the employment of which is every day becoming more common in photography, whether for the purpose of carbon printing or the production of certain enamels, is far from being innocuous to health. Its local action sets up an irritation which first becomes manifest upon healthy skin by an eruption of a pustulous character. Its action is favoured by scratches or chaps upon the hands of the operator, for bichromate of potash will enter the smallest wound, and the slightest abrasion of the skin will lead to ulceration, which rapidly spreads, and refuses to answer to any kind of treatment. Pustules, ulcerations, and such like wounds are not rare with those who work much with bichromate of potash. Moreover, the compound, in fine dust, if breathed with the atmosphere of the apartment, gives rise to inflammation of the mouth and stubborn colds in the head, which, if repeated, frequently end by bringing about, after a time, a special, characteristic lesion. The perforation of the diaphragm of the nose, by means of a fistulous communication between the nostrils, also arises.

Photographic operators who have to manipulate bichromate of potash do not employ it so frequently, or for a period sufficiently prolonged to give rise to grave accidents. Nevertheless, its use may bring with it colds in the head and inflammation of the eyes and eyelids, as happened in a recent case where a man was in the habit of carrying his hand to his eyes after having handled crystals of the salts.

To prevent inflammatory actions of this kind, it is well, every time bichromate of potash is used, to wash the hands, face, eyes, mouth, and nostrils with water very thoroughly.

The action of bichromate of potash taken internally is that of an irritant and violent poison. Poisoning by this salt is characterised by inflammation, or even cauterization of the mucous membrane of the mouth, throat, and stomach, giving rise to painful cramps and to vomiting, often mixed with blood. Absorbed and carried into the circulation, it renders respiration difficult, brings about chilliness in the hands and feet, accompanied by diarrhoea and choleraic symptoms. After a time an intoxication sets in, with more or less complete paralysis of the limbs, during which death supervenes.

If any accident takes place from the use of bichromate of potash, or any attempt at suicide, the patient should be given at once, without awaiting the arrival of a medical man, a dose of lime water mixed with albumen. At the

same time warmth should be restored to the body by vigorous friction of the arms and legs, using, for rubbing the limbs with, alcohol mixed with ammonia in the proportion of five grammes of ammonia to one hundred grammes of alcohol.

*Bichloride of Mercury.*—Bichloride of mercury is still known under its old name of corrosive sublimate, by reason of its violent corrosive action. It may be rarely used in photography now-a-days, but, at any rate, it is employed often enough to make it worth while to put operators on their guard who may have anything to do with it. A solution of bichloride in contact with a broken skin brings about a sort of local gangrene, which attacks the tissue very severely. Absorbed through a healthy or ulcerous skin, it may cause abnormal secretion of the saliva, accompanied by a softening, swelling, and ulceration of the gums, and noisome breath. In these cases it is well to employ chlorate of potash dissolved in water, which is used either as a lotion for the wounds, or for gargling, or in draughts to prevent salivation and its attendant ills. If taken internally, bichloride of mercury influences the stomach, gives rise to inflammation of the mucous membrane, vomiting of blood, &c. The best antidote in such a case is, without doubt, white of egg (albumen) mixed with sugared water or milk. Iron or zinc filings may also be taken mixed up in honey.

We have confined our remarks in this work to the consideration of the atmosphere of photographic studios, the character of the work, and the materials employed, which have a dangerous influence upon the health. Other chemical compounds used in photography may exercise, although in a lesser degree, an influence upon the health of photographic operators, and there are also certain circumstances in the carrying on of the profession that we have omitted to take notice of in this communication on photography from a sanitary point of view.

Our peculiar position as medical adviser to the French Photographie Benevolent Society permits us to make a daily study of the health of photographers, and at some future time we hope to extend and complete the work we have begun. Such as it is at present, we trust it may be of assistance to photographic operators, with whom, two years ago, we first became acquainted, many patients whom we then knew having since grown into personal friends.

## Correspondence.

### DR. VOGEL'S DISCOVERY.

DEAR SIR,—The last number of your journal brings me the good news that Dr. Vogel has obtained lines in the yellow and red portions of the spectrum. I have no need to see the impressions that have been forwarded you, to believe this. I have the honour to know Dr. Vogel personally, and have never doubted his good word, as, indeed, I yesterday wrote him.

It is evident that as Dr. Vogel has obtained the lines in the yellow portion of the spectrum, the argument I used—that is to say, that his results were obtained through diffusion, by reason of the transparent nature of his prisms, or the reflection of the actinic colours upon the interior walls of the spectroscopic eyepiece—falls to the ground.

At the same time, I must complain that Dr. Vogel has not described his experiments with sufficient precision. He announces to the photographic world that it is sufficient to colour a film of bromide of silver to render it all at once sensitive to that part of the spectrum corresponding to the colour in question. This is a radical discovery. But if the colouring must not be too strong, nor too weak, as we learn to-day, the new law is less evident to physicists. And in any case our friend Vogel should have specified these special conditions.

You will agree with me, I know, Mr. Editor, when I ask

Dr. Vogel to publish in your journal, as soon as possible, an exact account of the manner in which the sensitive film must be prepared to retain an impression of the spectrum, which till now it has been impossible to secure.

Everybody cannot obtain the dry plates of Colonel Stuart Wortley, the preparation of which, I believe, by the way, is a secret. If to secure the yellow spectrum these plates are absolutely necessary (which I do not suppose to be the case), then Dr. Vogel ought not to wonder if his discovery is contested, or at least doubted.

In any case, I may add that as soon as I am acquainted with Dr. Vogel's precise manner of working, I shall repeat his experiments, and shall be very happy to be able to declare that I have been successful.—Believe me, &c.,

Ghent, 4th July.

DR. D. VAN MONCKHOVEN.

[Dr. Vogel will, we doubt not, hasten to give, as precisely as circumstances will permit, definite formula for the depth of staining necessary to secure the best result. The plate with which he has favoured us, and his note thereon, show that whilst excess of colour is destructive of all effect, there is a point of dilution, which can probably be stated, at which the maximum extension of the spectrum can be secured; and this Dr. Vogel will doubtless give in response to Dr. Van Monckhoven's courteous request.—Ed.]

### THE GELATINE EMULSION AND CAPTAIN ABNEY'S PROCESS.

DEAR SIR,—In accordance with the wish for experimental notes of the new dry plate process with gelatine, my experience is the same as your last correspondent, namely, the difficulty in getting an even coating on the glass, so that I was unable to give it what will seem a fair trial; but as soon as I tried the process suggested by Capt. Abney, I abandoned all other experiments, as with it I have never lost a plate, and the results are far better (in my judgment) than any emulsion in softness and delicacy. I enclose print from a negative taken this morning—a difficult subject, comprising white rails and heavy shadows, with foliage, and yet all developed without hardness. True, there is a good deal of trouble in preparing the plate, but I imagine nothing good can be obtained without it. I have tried mixing albumen, beer, gallic, &c., as recommended to make one bath, instead of using them separately, but must prefer the effect of the latter.—I am, dear sir, yours truly,

F. R.

### KEEPING QUALITIES OF URANIUM PLATES.

SIR,—As many of your readers use my uranium emulsion process for dry plate work, the following record of an experiment will be of interest to them.

You will remember that I have more than once called attention in your columns to the fact that the presence of nitrate of uranium in an emulsion gave great keeping qualities to the plates prepared therefrom, and I tested this point crucially as follows.

In August last, I was doing some work on plates twenty-four by eighteen, and having three left over, I did as follows. In connection with dry plate preparation, I have a cupboard heated to 110°, and which remained at that temperature four days and nights in every week; during the rest of the week the cupboard is at the normal temperature of the air, and in more or less a damp atmosphere, as it is in the room where the washing of the emulsion plates is carried on. The three above-mentioned plates have remained in that cupboard, untouched, from August last till three days ago, and I send you a negative taken on one of them. You will note it to be as brilliant and perfect as a negative can be, and I have been unable to find any process other than my own able to stand this prolonged high temperature and change to a damp atmosphere. All plates of other kinds tried under the same conditions by me at various times have broken down under the ordeal.

Let me, then, strongly advise those desirous of making reliable, long keeping, and highly sensitive dry plates to

use nitrate of uranium in the emulsion, and if they make bath plates, to use it either in the collodion or the bath.—  
Faithfully yours,  
H. STUART WORTLEY.

July 8th.

[The negative forwarded is clean, brilliant, and in every way technically excellent.—Ed.]

## Proceedings of Societies.

### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE sixth monthly meeting for the present year took place on Tuesday, the 30th ult., at No. 15, Oldhall Street, the Rev. T. B. BANNER in the chair.

The minutes of the previous meeting were read and passed, and Mr. W. B. Roberts and Mr. L. W. Weber were elected members of the association.

THE SECRETARY gave an account of the excursion to Rhydy-wyn, and prius were exhibited of the views taken.

Mr. ATKINS said his negatives were taken by Mr. W. B. Bolfen's process. He was much pleased with them, and had no doubt they were an improvement on the old way of preparing the plates.

THE SECRETARY read a communication from Mr. P. Mawdsley on the development and manner of using the new Liverpool dry-plate emulsion.

Mr. ATKINS exhibited one of Mr. Janin's photographs in bas-reliefs. He (Mr. Atkins) stated that he had sent, as per advertisement, 7s. 6d. "for specimen with instructions," to Mr. J. Solomon, Red Lion Square, but in reply only received the print exhibited and terms on which copies from photographer's own negatives could be obtained. He (Mr. Atkins) complained to Mr. Solomon that he had paid for instructions, but could get no redress.

Some surprise was expressed by the members that so respectable a house did not at once rectify a mistake when an advertisement was so misleadingly worded.

A print, and also a negative, was handed round, which had been sent by Mr. W. H. Warner, of Denbigh, for inspection. The negative—a church interior—was a curiosity in photography by reason of its having an inverted copy of the distant east windows seemingly floating a short distance from the camera, showing distinctly the window panes, &c., the inverted windows and the windows proper being the same size on the negative.

THE SECRETARY read a communication on the above subject from Mr. Warner (see page 328). A discussion arose, but no definite conclusions were arrived at about the subject of the paper.

A vote of thanks was passed to Mr. Warner for his communication, and also for a beautiful 10×12 print of the now-celebrated Denbigh reredos, which Mr. Warner had kindly presented for the association's album. The print was much admired; for, though very difficult to take, owing to the cross lights in the church, it was as perfect as if taken in a studio.

Some gelatine and other negatives were exhibited by Mr. W. H. Kirkby, and Mr. Cooke showed some prints taken on Durand's paper when quite discoloured, and afterwards kept fourteen months before toning. They showed very little difference from prints prepared in a more rapid manner, and were quite passable.

The meeting was shortly afterwards adjourned.

## Talk in the Studio.

A LIBERAL OFFER.—Mr. W. J. Stillman, writing to the *Academy*, says:—"Looking over the Schliemann, and some other almost equally bad recent photographs, I can only believe that scientific men to whom photography would be useful are hardly aware that it is so simplified by recent practical discoveries as to put it quite within the power of any tourist, or student of archæology, geology, or any other science in need of illustration, to carry, in the compass of a foot cube, all the apparatus and material needed, and to learn (with average common sense) all the operations involved in the simplest forms of the art in two or three hours' application. I should be most happy to put any student of science in the way of judging of the truth of what I say, without any further expense or trouble than is involved in a visit of an hour any bright day when I am at home. This certainly is a subject on which 'they who have light should impart it,' and I shall be only too happy to put what I know at the service of science."

THE TRANSIT OF VENUS.—The *Times* says: "Captain W. de W. Abney, R.E., writes to us from St. Margaret's, Rochester:—'In your notice of the preparations made for the Transit of Venus Expedition, you have correctly announced that a dry-plate process worked out by myself has been adopted. I should like to add that, with a slight modification, the method of development which will be employed is that introduced by Colonel Stuart Wortley—viz., the use of the strong alkaline developer. As to the Colonel belongs the secret of putting into the hands of the photographers the powerful aid to rapidity with dry plates, I should be glad if you would insert this letter. I find my process is rather more rapid than wet plates when using it, while with the ordinary development it is but little more than half as quick.'"

PHOTOGRAPHY AT THE BOTTOM OF THE SEA.—Dr. Neumayer has recently exhibited before the Berlin Geographical Society a photographic apparatus designed for the determination of the temperature and of the currents at great depths in the ocean. The invention is composed of a copper box, hermetically sealed, and furnished with an exterior appendix made like a rudder. In the interior is a mercury thermometer and a compass, each enclosed in a glass receptacle in which are admitted traces of nitrogen gas. A small electric battery completes the apparatus. When the latter is allowed to descend attached to a sounding-line, the action of the current on its rudder causes it to assume a parallel direction, thus indicating the set of the flow by the relative position of compass, needle, and rudder. The thermometer of course shows the surrounding temperature. In order to fix these indications, a piece of photographic paper is suitably disposed near the glass cases containing the instruments. Then at the proper time a current of electricity is established through the gas in the receptacles, causing an intense violet light, capable of acting chemically upon the paper for a sufficient length of time to allow of the photography thereon of the shadows of the compass needle and of the mercury column. Within three minutes, it is said, the operation is complete, when the apparatus is hoisted and the paper removed.

DANGERS OF METHYLIC ALCOHOL.—The smell of methylated spirit is neither pleasant nor wholesome; fortunately photographers have not much need to use it. The most offensive form in which they come into contact with it is in using old collodion made with such spirit for cleaning plates. In any case, the following hints may be useful.—"Serious maladies," says the *Lyons Medical*, "have been engendered among the workmen in two industrial establishments by the employment of methylic alcohol—that is, wood naphtha, or alcohol derived from wood. The material is used in the finishing of felt hats, and of silk fabrics. Its action is directly upon the mucous membrane exposed to its emanations, and also, through the nervous system, upon the entire organization. The effect is first noticed upon the ocular *conjunctiva*, which becomes inflamed and injected, producing a sensation of sand in the eyes. A copious flow of tears and extreme sensibility to light (photophobia) follow, incapacitating the sufferer for work. Further symptoms include intense coryza, and inflammation of the pharynx and bronchial tubes, together with trouble of the digestive organs. Severe head-aches, and feelings of heaviness and depression, are always present. The rigour of the malady depends upon the extent to which the person is exposed to the alcoholic fumes. The workman who finishes the bottom of a hat is attacked more severely than the one who prepares the rim. It has also been noticed that cabinet makers who use the material in varnish are frequently attacked with tonic convulsions of the fingers, unknown previous to the employment of the alcohol."

COLOURED PORTRAITS.—The *Bookseller* for July notices that Mr. Canton has issued half-a-dozen carte-de-visite-size portraits, of Mr. Disraeli, Sir Stafford Northcote, Lord Salisbury, and other leading politicians, printed in oil colours, and considers that "these ought to be much more saleable at twopence each than plain photographs at a shilling."

BLOCKS FOR ENGRAVING.—A Bavarian firm, Gemeser and Walth, of Munich, says the *Peper and Printing Trades Journal*, "prepare wood blocks photographically for engraving by an adaptation of the permanent photograph process, in which lithographic ink is used, instead of by the old process with nitrate of silver. The advantage claimed is that of giving better tints of shades, the silver process giving only flat black shades, which were a great hindrance to good engraving." The same journal informs a correspondent the

"the system is now almost universally adopted by the illustrated newspapers of photographing the artists' drawing on the block for the wood engraver."

**SPIRITUALISM.**—An enterprising American publisher some time ago announced an edition of the Bible with photographic portraits of Abraham, Moses, David, Jesus Christ, and the Apostles. Apparently there is no difficulty in procuring them, for the *Spiritualist* of June 19th furnishes a portrait of a Medium and "the Spirit," taken from an instantaneous photograph!—*Bookseller.*

**A LARGE PHOTOGRAPH.**—An American contemporary refers to an enormous photograph by Messrs. Paxton and Co., consisting of an enlarged copy of an engraving about 24 by 30 inches. A negative on an 8 by 10 plate was first taken of it, and the enlargement made to 13 feet 6 inches long by 9 feet high, being produced in three vertical sections. The exposure of each section was twenty seconds, the development process being used. The negative, which was an admirable one for the purpose, was made by Mr. Bierstadt.

**To Correspondents.**

**FAIRPLAY.**—We have not space for further controversy on the subject. The pretended extracts from the *NEWS* and *YEAR-BOOK*, printed in parallel columns to give an air of accurate comparison, are not, as any one may see, extracts, but garbled compilations; and if they were strictly accurate, would prove nothing. As we can afford to smile at such petty misrepresentation, our correspondent may be content to let the matter drop.

**J. WILSON.**—In order to enable us to judge properly of the effect of the retouching, you should have sent us a print taken from the negative before retouching, for comparison. The retouching is smoothly done, but the face is a little flat; whether this is due to lighting or other photographic causes, or to excess of retouching, we cannot say without means of comparison. 2. The toning and general quality of the print are good. 3. If you are satisfied with your rolling press there is no need to change, but if it is not efficient you will find the burnisher excellent.

**A SUBSCRIBER.**—Mr. Stillman's Manual is published by C. D. Smith and Co., Fleet Street. 2. The use of spirit in the printing bath is an old method approved by many practical men. Mr. England has used it for years. He uses it at the rate of about three ounces in each pint of water; that is, he uses seventeen ounces of water and three ounces of spirit. So far as we remember, he uses methylated spirit, which answers perfectly, its unpleasant smell being the only objection. In no case need absolute alcohol be used.

**Tyro.**—Most samples of chloride of gold are acid, and the use of prepared chalk is the simplest and safest method of neutralizing the acid. Mr. Bovey's toning bath has generally been found successful.

**UNFIXED.**—It is possible to print from an unfixed negative, but your simplest plan will be to run an edging of wax or black varnish round the film, and then fix and wash in the usual way.

**A. B.**—So far as we can judge from the scraps of prints enclosed, the stains are due to imperfect fixation, or, at least, the stains seem to be caused by decomposed hyposulphite of silver, and are similar to the results of imperfect fixation. Some of these are suggestive of finger marks, and may have arisen from the fixed prints having been handled, before perfect washing, with fingers which had touched nitrate of silver. This might not produce a visible mark at the time, but a trace of hyposulphite of silver might thus be formed in the print, which would eventually decompose, and cause a yellow stain.

**HONEST ENQUIRER.**—The story has been told often enough; we have ourselves several times repeated the exact details. M. Gaudin did experiment with collodion emulsions of iodide, bromide, and chloride of silver in 1861, which he termed "photogenes." With the two former salts he obtained promising results; with the chloride of silver, as he himself stated in his own journal, he found it impossible to succeed. The journal to which you refer practically charges him with nuthuth when it declares he did that which he himself denied. The earliest account of emulsion experiments appeared in the *NEWS* in 1860, when some crude experiments by H. Bellini were described. Next came those of M. Gaudin, and about the same time some by Captain Dixon, ourselves, and others, with iodide and bromide of silver for negative purposes. The first successful introduction of a process, as distinct from tentative experiments which led to nothing, was the bromide process for negatives of Messrs. Sayce and Bolton, and contemporaneously therewith our own collodion-chloride process. The theory to which you refer as "unjust, if not absurd"—which is clearly both—would give to Mr. Bellini the origin of the collodion-bromide negative process! For other details we must refer you to back volumes of the *NEWS*. The historico-controversial aspect of the question has occupied more than enough space.

**B. D. M.**—There are no certain means of restoring a faded print. Several plans have been tried, and in some cases a decided improvement is effected. One method consists in immersing the print in a strong solution of chloride of gold. This, to some extent, removes the yellowness of the whites, and gives a fresh, purple bloom to the dark portions of the print. Saturating blotting-paper in a solution of bichloride of mercury, and placing the faded print between folds of the blotting-paper, sometimes effects an improvement. We are aware of the fact that many of the old sulphur-toned prints remain in perfectly good condition, whilst more recently produced gold-toned prints have faded. This is one of the puzzling problems of photography. The precise conditions of permanence in conjunction with sulphur toning have never been definitely ascertained. Fading in gold-toned prints is doubtless due to imperfection in the fixing or washing conditions; but on what precise point the imperfection with any special print arises could only be ascertained by careful investigation of particular cases.

**SALT.**—You may use a strong solution of salt after toning, and before fixing, with advantage, rather than with any risk of injury of any kind to the prints.

**R. S. T.**—The scratchy lines from the drag of the brush arise from the film being too moist, which may arise from under-exposure, too much glycerine, or a too moist atmosphere. Dry the plate again by heat when you find this the case. Re-grind, and carefully sift your plumbago. Patience and experience alone can ensure success. See an article in the present issue.

**CAMBALLO.**—See answer above.

Several Correspondents in our next.

**METEOROLOGICAL REPORT FOR JUNE.**

BY WILLIAM HENRY WATSON

Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

Date.	In shade, Morning	11 a.m. Noon.	Night.	In Sun, Noon.	Direction of Wind at 9 a.m.	
1	56°	58°	58°	—	S.	Rain a.m.
2	62	58	56	—	S.S.W.	Rain a.m. and p.m.
3	58	58	58	—	W.	Fair and sunny. Very clear this evening
4	59	61	57	—	S.	Fair. Gloomy. Fog this evening
5	56	59	55	—	S.	A little rain this morning. Sunny afternoon
6	57	59	55	—	W.S.W.	Fair, sunny, and clear
7	55	61	55	—	N.W.	Fair and sunny. Very clear this evening
8	61	65	58	—	S.S.W.	Fair, clear, and sunny.
9	64	64	60	—	S.S.W.	Fair. Gloomy. Strong wind this evening.
10	53	59	52	—	S.W.	Fair and sunny. Windy
11	59	62	47	—	W.S.W.	Storm of rain and wind. Sunny afternoon
12	52	56	50	—	S.W.	Fair and sunny. Frost late last night or early this morning.
13	54	—	50	110 5	E.	Fair, sunny, and clear
14	58	65	56	106	S.S.E.	Fair, sunny, and clear
15	60	66	56 4	120	N.W.	Fair and sunny
16	57	65	56	117	N.N.E.	Fair and sunny. Very windy this evening
17	59	71	57	120	N.	Fair and sunny. Windy this evening
18	60	72	58	128	N.W.	Fair and sunny. Rather hazy
19	58	61	60	110	N.	Fair and sunny. Rather hazy
20	58	61	53	109	W.S.W.	Fair and sunny. Rather cloudy
21	58	68	54	123	S.W.	Fair and sunny
22	66	62	56	103	S.W.	Fair and sunny
23	64	61	57 7	—	S.	Showers a.m. and p.m. Gloomy all day
24	62	64	57	103	S.S.W.	Fair and sunny all day. Heavy shower 11 p.m.
25	62	62	53	119	S.	Rain a.m.
26	57	68	53	—	S.	Fair, sunny, and clear
27	53	65	53	99	S.W.	Fair and sunny
28	57	65	57 6	107	S.S.E.	Fair and sunny. Rather hazy
29	68	68	57	—	S.W.	Fair. Gloomy. Distant thunder p.m.
30	62	63	58	—	S.W.	Heavy rain a.m. and p.m.

From the above data we have as follows:—

	Mornings.	Noons.	Nights.
Maximum temperature in shade during the month	68°	72°	60°
Minimum ditto ditto	52	56	47
Mean ditto ditto	58.9	63.3	55.4
Maximum temperature in direct rays of sun	—	128	—
Minimum ditto ditto	—	99	—
Mean ditto ditto	—	111.8	—
Number of days on which rain fell	...	...	7
Number of fair days	...	...	23
Number of fair days on which it was sunny	...	...	20
Number of fair days on which it was gloomy	...	...	5

Wind from S.W. and S. prevailed.

Vegetation has suffered very much from the want of rain, and the hay crops are much below the average.

• These observations were taken in direct rays of sun, and shaded from wind.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

INTENSIFYING NEGATIVES—A MONUMENT TO PAUL PRETSCH—A NEW BASIS FOR COLLODION PRINTS—THE PARIS SALON PHOTOGRAPHED.

*Intensifying Negatives.*—Several methods of rendering negatives more vigorous or dense have been suggested, not involving the employment of intensifying solutions, which some people look upon with great distrust. Mr. Blanchard was one of the first to suggest securing density by allowing the light to act upon the unfixed image, and we believe that for some years past he has employed this method in the production of the beautiful portraits for which he has become so famous. Another plan is to superpose two thin negatives, and thus obtain a vigorous, and, at the same time, delicate, result. A third process, recently suggested, is to coat the back of the fixed and varnished negative with a bichromated gelatine mixture, and allow the light to penetrate through the image to the sensitive film below, and, after a time, to wash and fix this secondary image, which aids materially in printing. If the negative in the first place happened to be a weak one, the non-actinic yellow tint, as also the bichromate image itself, imparting considerable vigour to the cliché. Another plan is now brought forward by M. Klinger, of Brannan, in Germany, which is similar to Mr. Blanchard's, and consists in exposing the unfixed image to light under a pale yellow glass, after having carefully wiped the reverse side, and freed it from any spots and blemishes that may exist. The negative is dried, and if not then sufficiently dense, it is again exposed as before. It is afterwards fixed and varnished in the ordinary way.

*A Monument to Paul Pretsch.*—Paul Pretsch is to have a monument erected to his memory in Vienna. This is good news, for it may have the effect of keeping in the remembrance of future generations the name of a worthy man, who worked hard to establish a practical photo-engraving process. Unfortunately his work never got beyond the experimental stage, and although many pictures of his have been circulated and printed which amply prove how very near he was to success, he never attained it. Unfortunately, his results just fell short of being good, and there was always some little more perfection required. However, as the Vienna Photographic Society are determined that no efforts shall be wanting on their part to perfect the process, and to this end have offered prizes, and instituted other means of encouragement, we may hope that before long Paul Pretsch's photo-galvanic process may be worked out in a thoroughly practical manner.

*A New Basis for Collodion Prints.*—A simple manner of producing portraits or other photographs upon a milk-white ground, similar to the well-known Eburneum pictures, is to float a collodion positive upon a substratum of collodion and white lead. Very finely ground white lead is shaken up in a bottle with some thick normal collodion, so as to form a beautiful creamy emulsion, and this, poured upon any suitable substance—such as a thin metal plate, a stiff smooth fabric, or similar basis—yields a smooth uniform surface of the purest white. The positive collodion image is removed from the glass plate in the ordinary manner, and the white tablet slipped under the image as it floats in the water. When the image has dried—it is stretched uniformly over the tablet by means of a soft brush—another application of collodion is made, to cement the picture down. For collodion enlargements, which are generally a little hazy and feeble, a basis of this kind is peculiarly fitted, and as the whole surface of the white lead is protected by one or two coats of collodion, there is little danger of its being attacked by the atmosphere.

The normal collodion used must be very thick, and the amount of lead added just sufficient to give it a creamy consistence; if a large quantity of white lead is added, the film is too rotten to hold, and in this case a preliminary coating of collodion should be applied before the image is floated on to it.

*The Paris Salon Photographed.*—MM. Goupil et Cie. are making good use of the Woodbury process in Paris. All the principal paintings of this year's Salon (the Royal Academy of Paris) have been photographed, and copies of various sizes are selling in hundreds and thousands. Series of ten reproductions are published at a time, and as many as six of these series have now been issued. The ten photographs, something like cabinet size, are to be had, neatly mounted and enclosed in a portfolio, for ten francs; and those who desire it may obtain photographs of the picture of larger dimensions at the rate of ten francs a piece. This is a trade in which photographers in England cannot, unfortunately, engage, for artists will not part with their copyrights so easily; and yet, when it is considered what a very few of the pictures exhibited are ever engraved, it is very questionable whether our English painters act wisely in the matter. All the popular pictures in the Academy are invariably reproduced in our illustrated journals—in the *Illustrated London News*, in the *Graphic*, and elsewhere—and the number of copies that are thus distributed certainly do more good than harm to the artist's reputation. Now in Paris, the numbers of photographic reproductions sold of pictures are so great that both artist and publisher secure a good profit, for it stands to reason that by selling a picture a dozen inches long for ten francs, a very good margin remains to the producer, especially when a mechanical process is employed for printing. We feel certain that artists in this country would gain both fame and money by allowing their works to be cleverly copied in the camera, and there cannot be a doubt that in a very few years more this course will be as universally adopted in England as it is abroad. Photographs can never compare with the original painting in colours, and the issue of monochrome copies only tends to enhance the value of the original.

### AMERICAN CORRESPONDENCE.

PHOTOGRAPHY IN CALIFORNIA—A NEW WORK ON PHOTOGRAPHIC PRINTING.

*Photography in California.*—A few weeks ago the negatives sent to the publishers of the *Philadelphia Photographer*, in number about one hundred and fifty, to compete for the gold medal offered for the best three, were examined by the judges, and, to the surprise of all, the award was made to parties who sent their negatives three thousand miles to compete: Messrs. Bradley and Rulofson, of San Francisco, California. They sent six negatives of the same subject, all equally perfect, being absolutely without spot or blemish. They are among the purest specimens of photography it has ever been my good fortune to inspect. All there is in the print was produced in the negative. The retouching is so slight that it can scarcely be detected, and the beautiful gradations of light and shade are perfectly natural and spontaneous. For chemical effects, lighting, posing, and general artistic treatment, they deserve the study of all who feel that they are not yet as high up in the scale of excellence as they wish to be, and trust they may be benefited. I give below letters from Mr. Rulofson and his operator, Mr. Taylor, and a cut from a photograph of their operating-room, should you see best to present them to your readers. The latter, from the eight by ten print sent me, has a very inviting appearance, seems large, and well supplied with all appliances necessary for first-class work.

The modesty of our friends in speaking of themselves is as refreshing as their work is excellent. Their apparent

unconsciousness of having produced anything superior brings forcibly to mind the following paragraph from "Art Culture: a Handbook of Art Technicalities and Criticisms," by John Ruskin. Under "Art Laws," he says:—"While in painting, much knowledge of what is technical and practical is necessary to a right judgment, and while every great composition is in perfect harmony with all true rules, and involves thousands too delicate for eye, ear, or thought to trace; while it is possible to reason, with infinite pleasure and profit, about these principles when the thing is once done, yet all our reasoning will not enable any one to do another thing like it, because all reasoning falls infinitely short of a divine instinct. Thus we may reason wisely over the way a bee builds its comb, and be profited by finding out certain things about the angles of it. But the bee knows nothing about the matter. It builds its comb in a far more inevitable way. And from a bee to Paul Veronese, all master-workers work with this awful, this inspired unconsciousness."

The following are the letters referred to, and I am glad to see the operator recognized, and allowed credit for his part in the work.

Mr. Rulofson says:—

"I herewith forward to you a note from Mr. Taylor, giving our formulæ for working, and containing some of his views on the subject; but I must confess I would not have you understand that I endorse all he says on the subject of the relative quality of San Francisco work, nor the causes to which he ascribes the assumed superiority, while I would be slow to detract from the industry, perseverance, and skill of our photographer. I think it but fair to admit that they possess some climatic advantages not enjoyed elsewhere in America. I do not regard the light as superior in actinic power to that of the Atlantic States; but we do possess a more even temperature, the thermometer seldom rising above 75°, or falling below 60°, with a slightly humid atmosphere, presenting the most favourable conditions for delicate chemical processes involving the use of volatile substances. And California's proverbial modesty causes us to cast about for some natural cause to which to attribute any superiority which our friends may kindly ascribe to our productions.

"I send herewith a plan of our gallery, from the street entrance to elevator, to the roof; there are in all twenty-nine rooms, reasonably well adapted to their several uses. You will observe that we formerly occupied the corner building only; we then cut through into the adjoining building on Sacramento Street, and

later, effected an entrance into the one on Montgomery Street. We are now giving employment to thirty-four hands all told. We employ six Chinese; they are faithful, industrious, and expert, valuable aids in the mounting and finishing department.

"We made several attempts to obtain an interior negative of our reception room, of which we are proud, but failed, owing to the long exposure required, and the throng constantly interrupting.

"And now it only remains for me to say that I regret not being able to present some more interesting material for your consideration."

Mr. D. B. Taylor, the operator (which means the gentleman who makes the sittings and superintends the dark closet) says:—

"In reference to your request, I give you my formula by which the prize negatives were made. It is an old and long-used formula, but I think there is no better when carefully used.

COLLODION.

Ether and alcohol	... ..	equal parts
Cotton	... ..	6 grains to ounce
Iodide of ammonium	... ..	4½ grains
Bromide of potassium	... ..	2 grains

SILVER BATH—40 grains, slightly acid.

DEVELOPER.

Water	... ..	96 ounces
Iron	... ..	6 "
Acetic acid	... ..	10 "
Alcohol	... ..	6 "

"The above is the formula I have worked for the last four years, all the time I have been with Bradley and Rulofson, and our negatives, in quality, improve from year to year—not by trying every new-fangled notion that comes along, but by giving our closest attention to the details of the process. I have worked in photography for the last sixteen years in the Eastern and Western States, and have met more thorough-bred photographers in San Francisco than I ever saw in my life before. This city has the reputation of making some of the finest photographs in the Union, and I might say the world, and it is all due to the careful hard workers in photography. The climate has nothing to do with it. Work—work does it; work is the word with us in San Francisco.

"I have made an interior view of my operating room and lights, showing the position the camera and sitter were placed under the light, when the prize negatives were made. I forward you a copy."

The July number of the *Philadelphia Photographer* will carry your specimen print from the prize negative, and I believe it will bear out all I have said about it.

When in Europe, I found that the pictures of our Yosemite Valley, and "big trees" of the Maniopa Grove, were quite in demand. One of the most successful photographers in the wild sections named is Mr. J. J. Reilly. He has sent me his working formulæ, and I append the same for the use of those who have similar work to do. He also mentions some of the difficulties with which he has had to contend. He says:—

"Since I left Niagara, I have been over a great portion of this coast; in the Yosemite Valley especially, for the past four summers. I have also made a few trips outside of the valley, crossing the summits of the wild Sierra Nevada Mountains, and also running some risk of being scalped by the Indians; also ascending the tops of the highest mountains, ten thousand feet above the sea, where lay in places from five to ten feet of snow right in the month of August, and no water to be found short of one or two miles to wash negatives with. This difficulty was overcome by building a brush fire and heating stone in it; then filling a bucket full of snow and placing the hot stone therein; in a few minutes we had plenty of soft water, and by cutting a top off one of my socks, and tying it around the faucet, I was enabled to get clean water and so do clean work; and on that trip of four weeks I made some fine cloud effects. But I can get no more for this class of work, from these hard-earned negatives, than if they had cost me nothing, and the pictures were of the poorest kind.

"My way of working is as follows:—I am using a pair of 3½-inch focus tubes, known as the imitation Dallmeyer's; also a pair of genuine Dallmeyer's wide-angle 2½-inch focus. With these two pairs I do all my work.

"My collodion is as follows:—

No. 1.—Plain collodion	... ..	1 ounce
Iodide of cadmium	... ..	4 grains
Bromide of cadmium	... ..	4 "
No. 2.—Plain collodion	... ..	1 ounce
Iodide of cadmium	... ..	7 grains
Bromide of cadmium	... ..	3 "

These two can be so mixed as to save the most delicate clouds. If

No. 1 work too thin, mix with it a little of No. 2 for cloud effects; if not for clouds, mix in equal proportions.

No. 3.—Plain collodion ... .. 1 ounce  
 Iodide of ammonium ... .. 6 grains  
 Bromide of ammonium ... .. 3 ..

"This will much benefit your collodion by mixing one-third of No. 3—that is, if no clouds are to be taken. In making my collodion, I use equal parts of ether and alcohol, but I dissolve my iodides and bromides in the alcohol first, and I use from 3½ to 4 grains of gun-cotton to the ounce.

DEVELOPER.

Double sulphate of iron and ammonia ... 1 ounce  
 Water ... .. 20 ounces  
 Acetic acid ... .. 2 ..  
 No alcohol.

REDEVELOPER.

Pyrogallic acid ... .. 3 grains  
 Citric acid ... .. 2 ..  
 Water ... .. 1 ounce  
 No. 2.—Nitrate of silver ... .. 20 grains  
 Water ... .. 1 ounce

Twenty drops of No. 2, in one-half ounce of the pyro, poured over the negative after fixing and well washing, will bring it up to the required intensity. This solution may be poured off and on the plate till enough intensity is obtained, but must not be used a second time. But the bottle must be washed clean before developing a second plate. After fixing the negative and then redeveloping, it don't dry any more intense. Always keep a weak solution of sulphuret of potash on hand, so that should the pyro stain or turn your negative a scarlet colour, by flowing the plate with the sulphuret once or twice this colour will leave. Wash well, and set up to dry; then it is ready for varnishing."

*A New Work on Photographic Printing.*—Photographic printing, it is generally acknowledged now, should have the same care and attention as the making of the negative. Nearly all our best photographers admit that the printing department has been too much neglected. No pains or expense have been spared to construct the best skylights, work the best chemicals, and the most approved formulæ; to employ men of the highest abilities in the dark room, under the skylight, and in the retouching department; all that the negatives may be strictly first-class. Oftentimes all the energies of the proprietor are given to the negative department. He buys books on chemistry, light, art, and studies them all diligently; but the printing department is left, in a great measure, to take care of itself. No books are ever bought for the printer; he may not have an opportunity to even see the monthly journal his employer takes for his own especial benefit. The printer picks up what he can, and does his best; but neither he nor anybody else dreams that any artistic skill or study are required to produce a good print. If the prints are not right, the negatives must be at fault. They are all printed on one brand of paper, all prepared in the same way, and some prints turn out well, while others do not; if there be any fault, it is attributed to the negatives. This is the way it has been to a great extent. There has been a want of union, or harmony of working, between the departments. The negative maker has often been surprised that some of his most beautiful work has turned out such miserable prints. He has often seen, too, that the proof from a negative, printed, perhaps, on any old piece of paper that came to hand, probably left over from the day before, would be better than any afterwards printed in filling the order. This would arise from the printer not understanding the conditions necessary to make the best print from that particular negative.

Mr. Hearn, as a practical man, has seen all these things, and, being strongly impressed with the importance of having more light in this direction, has prepared this book. It is mainly a transcript of his own experience; and as every thorough man in any business knows how much depends on what are often considered minor details, and which are often overlooked by experienced teachers, the explicitness of this work will be appreciated. It is an

important feature of it, and all who study it for information will find it a perfect text-book for the printing-room. There seems to be nothing omitted. Every condition and quality of negative, its peculiar features, how to study it, and the treatment it should receive in the process of printing, the selection and preparation of the paper, the effect produced by certain processes and methods of working, and every point, apparently from the first inspection of the negative to the finishing of the print, is anticipated, and the necessary instructions to cover all contingencies given. Any proprietor who will place this book in the hands of his printer will no doubt find an improvement in his work, and be himself relieved of much responsibility of looking after that department. It is especially adapted to those who are learning or striving to improve, though it is full of useful suggestions, and will be a great help in the hands of the most experienced. The author has been known for several years past under the *nom de plume* of "Young Printer." He is yet a young man, but by diligent study and observation has made himself a master of his business. The book is well illustrated, and contains also a specimen print by the author, from negatives by Mr. F. Gutekunst, of this city.

I draw attention to this work for the reason that it is a fact worth noting, that photographic printing has become of enough importance to require a work so elaborate as this to be published in its behalf. It is devoted solely to plain and albumen paper printing, and Mr. Simpson's collodio-chloride process. No doubt your publishers, Messrs. Piper and Carter, will have an early supply, and be able to fill all demands for it. EDWARD L. WILSON.

GERMAN CORRESPONDENCE.

ABOUT NEGATIVE VARNISH—ALBUMEN PAPER MANUFACTORIES—YELLOW SPOTS ON ALBUMEN PAPER—REPRODUCING NEGATIVES—ABOUT ENAMELLED BURNT-IN PICTURES—NEW APPLICATION OF POWDER PROCESS.

BY DR. VOGEL.

IT may appear as labour lost to write something new about negative varnish—particularly when writing to America, where good varnishes are by no means scarce, and where even inferior kinds, on account of the dry climate, do good service. It is different in the damp climate of Europe, and year in year out we hear complaints about the cracking of the film. "Such things do not happen with us," said an American friend to me. Happy America!

But there are certain shortcomings in varnishing of which I will speak now. It has most likely happened to every photographer that the picture, on being varnished, became dissolved; it was eaten away as soon as the varnish was poured upon it, and floated partially or entirely away with it. I observed this phenomenon ten years ago, and found that an addition of water to the varnish will cure the evil. One cubic centimetre of water to one hundred cubic centimetres of varnish suffices. When water is added to the varnish a precipitate is formed, which is removed by warming the varnish. This fact has led to the supposition that too strong an alcohol is the cause of the dissolving of the film; for it is well known that some samples of pyroxyline will dissolve in warm alcohol, and this is the reason why the same varnish will not dissolve every film, but only certain collodions. Ungar, in Vienna, has lately demonstrated that not only the alcohol, but also a certain percentage of turpentine in the varnish, causes this eating away of the film. Ungar found that a solution of twenty parts of turpentine in one hundred parts of water possessed strong dissolving power for collodion films—so much so that the film will always be dissolved when these conditions are present, and particularly when the plate has been warmed.

I remember a communication of our friend Simpson, which he wrote ten years ago, to the effect that oil of

turpentine may be used for dissolving cotton. At all events, there are several substances which will dissolve cotton which heretofore have been but little tried—for instance, acetone, nitro-benzole, &c.

Ungar's communication points to the fact that turpentine in the varnish exercises an injurious influence; on the other hand, turpentine is frequently added to varnish because it improves its quality in other respects. Ungar maintains that the ugly cracks and splits in varnish are avoided by adding turpentine. He speaks of a varnish which showed cracks one quarter of an hour after it had been applied, and which, by the addition of turpentine, became fit for use. Castor oil, which is also sometimes added to varnish, is said to be not near as efficient as turpentine. Ungar gives the following formulæ:—

Yellow shellac	...	...	...	2 parts
Turpentine	...	...	...	1 part
Dissolved in weak alcohol.				

Also,

Sandarac	...	...	...	1 part
Turpentine	...	...	...	$\frac{1}{2}$ "
Camphor	...	...	...	$\frac{1}{4}$ "

Plates which have been coated with the last-named varnish may be placed for weeks in nitric acid without the film being destroyed. In order to remove this varnish warm lye has to be used. Ungar states, further, that the lead pencil retouch adheres to this varnish without any further preparation.

I add some observations on the distortion of the film, due to the action of the varnish, sometimes in the shape of expansion, at others as contractions. It seems that this depends mainly on the character of the varnish which has been employed, for a mastic varnish which I tried recently did not expand the film in the least.

In my last letter, I wrote to you that all the Dresden albumen paper manufactories had been consolidated into a single joint-stock concern. It was at the time supposed that Trapp and Munch, in Friedberg, would also join in this arrangement; this, however, is not the case. Trapp and Munch remain independent, and use, as heretofore, Rives plain paper. Speaking about paper, I have to caution those of my readers who are smokers. Mr. Constant states that the small yellow spots, which we sometimes notice on the finished pictures, are caused by the ash-dust from cigars. He has noticed that in the centre of this spot a small grain is always perceptible, and that a yellow colour extends around it, which extends the further the larger the grain. This spot becomes visible after fixing and washing, but becomes prominent only after drying. Mr. Constant refers to the testimony of a lady photographer, who was much annoyed by these spots, until, finally, she forbid her workmen to smoke in the atelier, when the spots disappeared.

I myself do not smoke, and have never noticed these spots; but, on the other hand, I know several photographers here who smoke constantly, and who have never noticed these spots.

The process of Obernetter for reproducing negatives is much talked about. I have recently seen a negative portrait of the Emperor, which had been reproduced by Obernetter in an admirable manner. It is certain that not every one is able to reproduce by this process as successfully as Obernetter, who, by years of practice, has acquired an astonishing routine; and this seems to be necessary. His process is the same as the one which is employed in making enamelled or burnt-in pictures. I have met many persons who have tried this process, but did not meet with any success. Obernetter has published lately some interesting facts which explain the want of success. In making a porcelain picture a film of chromate of gum is exposed to light, and dusted over with the enamel powder; the plate is afterwards coated with collodion, and washed

finally with diluted acid, in order to remove the chromic salts. This acid is, according to Obernetter, the objectionable feature; it decomposes the pigment, which loses, in consequence, tone and lustre, and turns grey and ugly. This objectionable feature is at once removed if we employ in place of the acid, an alkali for washing the plate—for instance, a weak solution of soda or potash. Many persons torment themselves by making the solution in the dark, by dusting in the dark, and coating the plate in the dark, &c. This, however, is not necessary. The solution does not suffer by light; the dry film is somewhat affected by light, but only if the action continues for some time.

A copper or glass plate is coated with a thick solution of ten grammes gelatine, two grammes glycerine, four grammes bichromate of ammonia, and fifty grammes of water; when the plate has become dry it is exposed under a negative. After exposure the plate is dusted over with fine zinc-dust, such as is found in the zinc works, until the depths are strongly infected with it. When the plate has been sufficiently dusted, a part of the chromate is washed out with water, and this is continued so long as the water has a lemon-yellow colour; afterwards the plate is left to dry spontaneously. The remnant of the chromate remaining in the plate is just sufficient to make the gelatine film, by long exposure to light or heating to 150°, insoluble. When this has been done the plate is exposed to dilute muriatic acid, the zinc dissolves, and the resulting hydrogen reduces, in its nascent state, the insoluble gelatine into the soluble modification. The film is then washed with hot water, and we have a relief plate in which all the parts are depressed where the zinc-dust had been before—in other words, the shadows. This relief plate can be copied by the galvanic process. Unfortunately, the half tones, as well as the shadows, are depressed, and hence we have no half tones in the picture. But line drawings may be reproduced by this process in an excellent manner. This kind of work, however, is by no means pleasant, for the zinc-dust is injurious to health, and to inhale it cannot be avoided. If we work for half-an-hour at this process the consequences are metallic taste, loss of appetite, and tendency to vomiting. Partially, we can protect ourselves by the use of respirators. Two or three plates a day may be made with impunity.—*Philadelphia Photographer.*

## Recent Patents.

### PHOTO BLOCK PRINTING.

BY E. H. COURTENAY.

The following invention consists in a method of producing by photography blocks for surface printing. The specification is as follows:—

"This invention has for its object the preparation of printing surfaces by means of photography and hydraulic pressure, and by its means plates or blocks are engraved, surface or intaglio, that can be printed from by any of the presses in ordinary use, the subjects being taken direct from nature or otherwise.

"In the first place I prepare a suitable collodion containing oleate of silver and a powder that will not act injuriously to the collodion or silver bath; the powder I use for producing a negative for the purpose of giving a certain amount of granularity to the finished surface block is corn meal or any other similar farinaceous powder that will not disturb the delicacy of the negative film through the repeated washings the same is subjected to; or a mineral powder can be used, such as powdered glass or pure silic obtained from silicate of potash or ammonia; in fact, any powder can be used that will not injure the chemistry in the production of the plates,—the object of the use of the powder being to produce a kind of stipple in the negative film of a photograph from nature, and that of the oleate of silver to give sensitiveness and vigour to the negative, combined with a certain neat appearance of the film that assists to check the too energetic action of the light through the transparent parts of the negative in the production of the positive, which I prefer to take by transmitted light.

through the camera, with or from the negative in grain before mentioned.

"I do not confine myself to the use of a collodion containing any particular powder for the purpose of producing a grain or stipple; I sometimes use a composition in which is mixed a suitable powder for producing the granularity required; I also use plates prepared with suitable grain, according to the purposes required, either artificially or done by hand, which I afterwards impress on the soft metal plates. By this method I claim originality in producing photo-mezzotint, and photo-aquatint, as also line subjects to imitate chalk drawings, by hydraulic pressure.

"A soft metal plate is prepared with a grain suitable for the intended design, after which a relief photograph is transferred to the plate of a suitable thickness, the gradations of the photograph filling certain portions of the grained plate in lieu of the engraver scraping away the lights and tones in the usual manner; a cast is now taken with gutta-percha and electrotyped in the usual way, either solid or backed up with type metal, after which the face is cleaned, and the plate is ready for the press.

"I now proceed to take a transparent positive as follows:—I take a suitable collodion without the powder, the camera being adjusted to the size of plate or block required, and take a transparency in the usual way from the granulated negative. In the positive taken as above there are those conditions in it that are requisite for the production of a surface block: in stipple; or a grained plate can be used instead of the positive transparency in grain, the negative relief being transferred and impressed on to the grained plate; or a smooth plate can be used with a grain in the composition used for the negative relief, to obtain which I prepare a gelatinous compound of such a nature that when acted upon by light a photograph is obtained in negative relief from the positive above described.

"The composition I use and find most convenient is a mixture of gelatine, sugar, tragacanth, and starch, and a coloring matter—usually carbon—in fine powder or liquid Indian ink.

"I do not confine myself to one or any particular ingredient for the production of the photograph; any compound can be used in combination with chromic acid or any of its salts, such as bichromate of potash or ammonia, or any other sensitizing agent.

"I do not claim originality in producing a photograph in relief by using one or any of the substances herein-before mentioned.

"I claim originality in the method of producing a negative photograph in relief so that by pressure I obtain a positive in metallic relief that can be printed from to produce photographs at the ordinary printing press.

"I do not claim anything in common with the process known as photo-relievo, my process being the reverse of the one named above, inasmuch as the relievo process is intaglio, used with a special ink to suit the requirements of that process; but I claim the process of making surface blocks by photography and pressure, to be printed from by the ordinary methods of printing.

"To use the composition above mentioned I level a slab of glass, and place paper or any other support, with the back wetted, perfectly flat on the glass, and pour a sufficient quantity of the compound solution on to the paper, after which it is hung up to dry. When the sensitized compound is dry it is then rolled and placed under the positive in the photographic printing frame, or it is placed under a negative if for an intaglio plate, and submitted to the action of light; daylight is best; the electric light will do. When sufficiently impressed, which is determined by the strength of the light, it is taken from the frame and transferred to a type metal plate, the plate being highly polished; any other soft metal will do when the block is to be electrotyped. With the negative photograph now on the plate it is placed in warm water, the water being changed until the parts not acted upon by light are washed away; the plate is now dried, and the design in relief upon the plate is now ready to be engraved by pressure, which is performed as follows:—If the plate is inked at this stage with the roller it will deliver a negative print, the lights and shadows are reversed, the whites print black, and the blacks white; the plate is therefore put between two highly polished steel plates and placed upon the bed of the hydraulic press and submitted to very great pressure; the type metal plate is now as smooth as the steel plates between which it was pressed, consequently the parts of the design that were in relief are now sunk, and form the lights of the print; the smooth parts facing the steel plate being the design to be printed from in relief, the photograph is washed out of the plate that has been pressed, and the plate trimmed and mounted on a block in the usual way; it is

now ready for the press, to be printed from in the way usually adopted for printing woodcuts, excepting the difference that a photograph is used for the overlay instead of one cut by hand as for woodcuts. The photograph for the overlay is similar to the one used to engrave the plate in respect to relief, but it must be printed from a negative, care being taken that the negative is the exact size of the block required, and the print is transferred to paper and adjusted to the tympan of the press as is usual with ordinary overlays. By this arrangement it will be seen that the photographic overlay will register the photographic relief block, and according to the gradations of the photograph on the tympan of the press will be regulated the amount of ink delivered to the print.

"I also claim as original the method of engraving plates by photography and pressure as described above, by the negative photograph in relief, of all or any subjects that can be copied for the purposes of reproduction, such as engravings, drawings, pen sketches, water colour and other drawing, reprints of books, and all objects or subjects that can be photographed and engraved by the above mentioned process, as likewise the production of designs in silver and gold from printed matter.

"I now proceed in the description of the method by which plates can be reproduced from printed matter, and which I claim to be original. A negative is taken as dense as possible from the subject required in block, and a transparent positive from that negative, likewise as dense as it possibly can be made by the ordinary means known to photographers; the positive is then used as in the method described for nature photographs on a composition made of similar ingredients, or the same as used for nature will do; the treatment is the same up to the pressure in the hydraulic press; after the design is forced into the plate the boldest parts of the work are treated with a solution of bichromate of potash and allowed to dry, after which those parts that were so treated are coated with strong gelatine and silex, and dried in a warm place in the light; the heat and light render those parts that were touched with the bichromate insoluble, and after washing away the upper part of the gelatine the whole is dried and again submitted to the press between the steel plates, causing those parts to be deeper where the gelatine has been applied; sulphate of iron, alum, or any powerful astringent can be used instead of the bichromate solution, or anything that will render gelatine insoluble. The plate is now washed in water containing an alkali for the purpose of removing the photograph, after which it is coated with zinc by electro-deposition in the usual way of depositing that metal; the plate is now inked up with a hard smooth roller, taking care that the lights are free from ink; it is then treated with the solution of nut galls, phosphoric acid, and gum, used by zincographic printers. The plate is used in either the press called the typo litho, the litho machine, or when mounted in the type press without the lights being cleared by cutting; or if the work is required to print at machine with letterpress the largest of the lights are cleared in the type metal or lead previous to electrotyping when that is required.

"The advantages gained by this method of preparing blocks or plates are, first, the rapid method by which the plates are made; the simplicity, ease, and certainty of production; and, next, the large number of photographs that can be printed at one operation."

**TRANSPARENT PARAFFIN**—The paraffin of commerce is a colourless, translucent substance, perfectly inodorous and tasteless. It floats on water, and has a density of about 0.870, and melts at about 113° to 149° Fah., forming a colorless oil, which, on cooling, again solidifies into a crystalline mass. It boils at about 695°, and volatilizes without decomposition. Paraffin does not absorb oxygen from the air, and is only slowly attacked by sulphuric acid, even at the boiling point of water. It is not at all attacked by dilute nitric acid, and only by the strong acid after prolonged boiling. In fact, chlorine, or any part of our most energetic chemicals, but slowly acts upon this curious substance, which may be considered to be as neutral to the general run of chemicals as our glass vessels. Lately it has been discovered that if paraffin be heated for some considerable time in a tube sealed up, the result is a more fusible paraffin, exactly similar in its apparent chemical composition, but much more soft and fusible—that, in fact, if the heat be continued for a considerable time, the paraffin being still under pressure, we obtain ultimately a perfectly transparent liquid paraffin.—*Scientific American*

## IMPROVING PYROXYLINE FOR PHOTOGRAPHIC USE.

VARIOUS methods have been proposed from time to time for getting rid of the impurities in pyroxyline, which lead to deranged baths, insensitiveness, and other troubles. Sixteen years ago, M. de la Haye proposed to precipitate cotton from collodion to secure absolute purity; all the impurities soluble in water, and which, being contained in collodion, find their way into the nitrate bath and contaminate it, being, by the process of precipitation and washing, removed. Many years after this suggestion, which never came into use, M. Camuzet made a similar proposal, which attracted considerable attention; but the process was too troublesome and costly for general application. Many years ago we tried, on a smaller scale, giving the pyroxyline a final wash in spirits of wine, and with good results. A recent letter from Dr. Vogel informs us that he has discovered a simple and excellent method of removing all impurities from the pyroxyline, which yields cheaply a better product than Camuzet's precipitated cotton. He contemplates protecting it by patent in this country. The best, simplest, and cheapest method of purifying pyroxyline, which has been published, was described by Mr. Gage, an American photographer, two or three years ago. His plan consisted in boiling the pyroxyline, by which the nitro-glucose and other substances soluble in water were effectually removed from the cotton.

A correspondent of our Philadelphia contemporary sends a suggestion for removing traces of acidity from pyroxyline which, he states, works most satisfactorily. We give the hints in his own words:—

“*Dodge*: Fume cotton before dissolving for collodion.

“*Theory*: Cotton, generally, is slightly acid, causing red collodion with even the best of chemicals. Ammonia neutralizes; washing in water and ammonia is troublesome, and takes time.

“*Experiment*: Made batch of 218 ounces collodion, using 3 ounces cotton; fumed strongly with ammonia, then aired a short time.

“*Result*: Splendid collodion, which, after three days, has but slight traces of colour, while another batch made at the same time of same amount, with same chemicals, but not fumed, was quite high colour in same length of time.”

## M. RODRIGUES' PHOTO-LITHOGRAPHIC PROCESS.

M. RODRIGUES, whose productions have procured for him a medal at the Paris Photographic Exhibition, has just made known to the French Photographic Society the details of his process, in which he employs tin foil for making his transfers to the stone or metal plate. Paper transfers are well known to suffer expansion, to a marked degree, when wetted, and allow, moreover, the thicker lines of ink to be pressed out of shape when the transfer takes place. These, as well as other minor defects, M. Rodrigues claims to have obviated by the employment of tin foil. The author thus describes his mode of operating:—

The tin foil employed is not thicker than a thin sheet of paper. The thinner it is the better, so long as it has not been rolled so thin that it shows minute holes over the surface. Unless it is very thin and supple, it is impossible to obtain fine clear transfers.

The sheet of tin foil is in the first place smoothed by placing it upon an unpolished but finely grained lithographic stone, and subjecting it to a slight pressure. Great pressure makes the metal less supple, and augments its tendency to tear. The employment of a very polished surface prevents the sensitive mixture from adhering perfectly to the metal when applied, whilst, on the other hand, too coarse a grain imparted to the surface interferes with the fineness of the design, and facilitates the formation of patches of greasy ink when rolled.

The tin foil, when rolled, must next be cleaned, and to facilitate this operation it is necessary to put a support under it. For this purpose a zinc plate, perfectly even and well polished, is employed, such as are used in photo-zincography. Its surface is moistened with water, the sheet of tin foil is placed upon it in the same manner as a sheet of positive paper is floated upon a silver bath, taking care not to produce creases or folds, lifting it up, and laying it down a second time if any such should be formed. If they cannot be altogether avoided, they are reduced as much as possible by pressing down the foil in those places, and the superposition of the two metallic surfaces is completed by slightly pressing the surface with a tuft of cotton-wool enveloped in a linen rag and moistened in water.

If the surface of the tin foil appears perfectly clean, it is sufficient to pass over its surface a clean rag soaked in a solution of soda, or potash, of ten per cent. strength. If it is necessary to use a more energetic method of cleaning, a little levigated chalk is added to the solution employed. Washing follows to remove every trace of the chalk, and the alkaline liquid and the bichromated gelatine solution is then applied by means of a very soft brush. This solution is composed of—

Gelatine of fine quality	...	...	40 grammes
Water	...	...	500 cub. cents.

The gelatine is allowed to swell in the water, and the solution afterwards completed by the aid of a water bath. Twenty grammes of bichromate of potash are then taken and dissolved in the same amount of water (five hundred cubic centimetres). When the two solutions have become tepid, they are mixed, and filtered, either through a sponge, or a double thickness of flannel. The best gelatine is that which, under these conditions, becomes a jelly at 20° to 25° Centigrade, without being at the same time very difficult to dissolve.

The bichromated gelatine mixture, spread upon the tin foil by means of a brush, should give a perfectly homogeneous film. The metallic surface should present a very uniform amber tint, without streaks or irregularities, and the coating should not be removable in patches, which indicates defective cleaning in the first instance. One should carefully avoid air-bubbles, which gave rise to small white points, as also particles of dust, every grain of which

attracts, by capillary action, the mixture when still liquid, and thus give rise to circles very lightly covered with the preparation.

As long as the bichromated gelatine is in a liquid state it is not sensitive, and therefore all the operations prior to coating the plate may be conducted in the daylight; but as soon as the gelatine begins to set, sensitiveness begins, and the rest of the work must be done in a studio protected by coloured glass.

It is necessary that the desiccation of the sensitive film be brought about rapidly, to prevent the crystallization of the chromium salt, and the production of any irregularities in the thickness of the layer of gelatine. To do this, the zinc plate upon which the tin foil is lying is heated, either over gas or upon a stove, taking care to keep it perfectly horizontal the while. When the surface has been sufficiently dried the sheet of tin foil is taken from its support, put upon a sheet of cardboard, and heated again to evaporate the water that has served to bring about contact. The tin foil is then ready for exposure under the negative.

Although the prepared tin may be kept for two or three days before being used, it is, nevertheless, best to employ it on the day of its preparation.

An ordinary printing frame is used, and the tin foil sheet is stretched upon the negative, perfect contact between the two surfaces being assured by passing over the foil a roller encased in flannel. Contact during exposure is maintained in the same way as in the case of ordinary positive prints, a little more pressure being employed for the purpose.

It is preferable to expose directly and perpendicularly to the rays of the sun, a pose of five or twelve minutes being the time required, or three times that amount in diffused light. If the cliché has an opaque ground, the exposure may be prolonged without inconvenience; but if, on the other hand, the glass is transparent, and the negative not perfectly clear, then the contrary is necessary. In the latter case success is more difficult, and it is best to operate with a feeble light.

The inking of the exposed print may be postponed till the next day; but it is always preferable to develop with as little delay as possible.

To ink the image, which is equivalent to its development, you commence by immersing the tin foil sheet in a large cold water bath, the impression uppermost, and it is applied in a moist state to a lithographic stone, perfectly even, destined to serve as a support during the process. During the operations no folds or creases must be produced, the design being kept uppermost. The flannel roller is passed over the surface to equalise the surface and to chase away the thicknesses of water between. Sometimes a sheet of blotting paper, well moistened, is applied, so that the absorption of the water may take place regularly. Then you pass over the gelatinized surface a printing roller charged with a mixture consisting of three parts lithographic transfer ink, and one part printing ink. The application of the ink in this way requires practice, for it is a delicate operation, and succeeds with more certainty the greater the skill of the operator engaged on the work. But little ink should be applied at one time, and the operation frequently renewed, and gum should only be employed at times quite exceptionally.

During the operation of inking, numerous accidents may happen. If the ink adheres slowly, and if much difficulty is experienced in applying it, this is because there is an excess of water present, or because the pose has not been long enough. The defect may be remedied by the employment of an ink more greasy and more liquid, although the best plan is to commence *de novo*.

If the groundwork of the image upon the tin becomes dirty, it is covered with a little dilute starch, or with a very weak solution of gum, or the spots may be rubbed with a sponge soaked in gum water. In this way the sur-

face is rendered less attractive to the ink; but this plan may have the effect of making the picture feeble.

If the exposure has lasted too long, and the surface takes up too much ink throughout, the ink is removed by the aid of essence of turpentine, and afterwards gum water is applied with care, and the print thus restored. A film of bichromated gelatine which is too thick is apt to tear under the roller; one that is too thin becomes covered with a veil of black points.

After this first inking, the impression is left for a couple of hours, and a second application is then made, when the surface is washed with a sponge and pure water; the print is wiped very lightly, and the tin foil sheet lifted from the lithographic stone and suspended to dry.

As soon as dry, the transfer is proceeded with in the usual manner. The work requires special care, but any skilled lithographer can perform it.

#### COMBINATION PRINTING WITHOUT CUT-OUT MASKS OR PATENT COMBINATION FRAMES.

BY W. T. BOVEY.

A REMARKABLE challenge, issued through the medium of an advertisement, is just now inviting photographers to try issue with the advertiser in a game of ingenuity and skill, the subject of the trial to be "a new invention of photographic combinations;" and the prize offered is a promise that the victor will be told how to do it—he having first discovered for himself the way it is done. Despite the amusing touch of Hybernicism evidenced in so liberal an offer, there may be noticed a deal of good sense and laudable forethought in Mr. Tilley's novel course of procedure, inasmuch as he proves himself desirous of ascertaining the nature of his claims ere he puts his secret into the market. If known by others, he will yield up his claims to originality, and will make his system publicly known; at least, it is so I interpret his meaning.

Now, in answering the challenge so boldly thrown down by Mr. Tilley, I have no intention of asking credit which may belong to the gentleman named. My sole aim shall be to show a way whereby the work of combination can be done, with all the conditions laid down by Mr. Tilley fulfilled.

First. The portrait or group may be taken in the studio in the ordinary way, save in the substitution of a white for the usually adopted background. If judiciously exposed and developed, a negative so taken would, if printed from in the shade, produce a print with background sufficiently untinted to answer all requirements. Remove the print from the frame, and place it upon a sheet of glass ready for the following operation, which must, of course, be conducted in a place where white light cannot gain admittance. Take water pigment (Venetian red will answer famously) finely ground and mixed to a consistency which will enable the brush to leave at each stroke a perfectly opaque coating. With this paint over the image with steady hand and great care. Keep within, rather than straggle without, the outlines of the figures. Dry thoroughly. Then place the paper in contact with the selected landscape, or other fanciful background, and print in the usual way. Withdraw the print from the frame, and, when ready for toning, immerse in water, and it will be seen that the first washing sweeps the entire pigment mask away; and the colour imparted by the gold in toning will be found none the poorer for the treatment, whilst a combination will have been obtained by the adoption of means so simple that any amateur would probably succeed at first trial; and if proper precaution be taken in selecting fitness of parts, a freedom from those incongruities known as contradictory lighting will add to the merits of the picture, which should contain no such outrage on truth and good taste.

It has occurred to me, whilst writing these lines, that a hint borrowed from Mr. Tilley's advertisement might be adopted and carried out in our journals with much of

practical advantage to their readers. Fertility of resource and ingenuity of contrivance are gifts which photographers, as a rule, are lavishly blessed with, whilst their stock of perseverance is proverbial, and their manifold difficulties are frequently conquered in out-of-kind ways. What the result, then, if we culled such experiences in pages that should be devoted to the publication of puzzling conundrums, by the managing director, say by preference, of the NEWS? The problems to be stated somewhat thus: "I have a negative with sky, by artificial means, so softly stopped out, that outlines of picture have nothing of scissors to show. How was the masking accomplished?" Brown knows all about the plan, and states how he has done it; Jones has been equally successful, although, in comparing methods, he works quite another way; Robinson has essayed to secure such results in many a trial, and burns to learn the secrets that lead to success; whilst all interested in the matter would enjoy opportunities of selecting for themselves the easiest; and ideas thus sown in fresh soil would propagate improvement, most certainly. Then failures might be introduced with a view of culling concealed principles from an examination of the proffered remedies. Fog, stains, stars, comets, together with those etceteras so familiar among photographers' woes, might be introduced in turn, and something new would be obtained from each subject under examination. Many other ways of utilising the plan would naturally occur to every interested mind, and I feel persuaded that a new vigour would spring up among the readers: secret-mongering would sink to a profitless discount, or would yield to what would prove a death-blow. There exist at this time a deal of faintheartedness, apathy, and misgiving in the world of photography; so pray do, Mr. Editor, make a trial of the plan I suggest, by giving space for a series of conundrums, if your readers having anything worthy of offer to show are willing to join in the fun.

### TOBACCO AS A PRESERVATIVE FOR DRY PLATES.

BY WILLIAM HY. WATSON.

No modern art or science can claim so many clear pathways to success as photography; nor can we wonder at this when we consider the numerous processes which spring up almost daily in its practice, and which are noted in our photographic journals from week to week, giving fresh employment for the experimentalist. Of course, according to the number of roads to which we may turn to arrive at the one destination, there will naturally be a little difficulty in selecting from the many that one which we may most advantageously pursue.

The greater portion of my time which I could devote to photography has for some time past been engaged with various experiments on a dry process in which I propose to use a decoction of tobacco as the preservative. As the results which have been furnished me by this process have been very satisfactory, I have much pleasure in sending to the PHOTOGRAPHIC NEWS this short notice in explanation, with the hope that it may induce others to give my preservative a fair trial.

The only novelty in the process is in the use of tobacco, in preference to various other substances which have been suggested from time to time for the preservation of the sensitiveness of the photographic film in a dry state. Tobaccos always contain to a greater or less degree various salts which are soluble in cold water, as sulphate and nitrate of potash, chlorides of potassium and sodium, &c., and occasionally, by way of adulteration, sulphate of magnesia, which, although not absolutely necessary, is well to remove from the tobacco before using. I give, as it may be interesting, the result of the number of determinations of these salts in several samples which I have used:—

No. 1.—Bird's-eye ...	7.45 per cent.
2 " " ...	8.53 "
3 " " ...	7.38 "
4 " " ...	5.10 "
5.—Cavendish ...	4.80 "
6 " " ...	4.70 "
7 " " ...	4.93 "

To remove these salts, add cold water to a portion of the tobacco (it is well to treat an ounce or two in this manner at once, so as to be ready for future use), allow it to stand for a short time, decant off, and "repeat the dose" once or twice, being careful to remove as little of the organic extractive matter as possible. Tobaccos vary in the quantity of nicotine which they contain, but in many cases we find from four to five per cent. In the use of tobacco as a preservative for dry plates, I believe the action is due considerably to this nicotine, which is naturally present. The preparation of the plate is simply this:—The plate, cleaned and coated with collodion, is sensitized in a nitrate of silver bath, slightly acid, and containing about thirty-five grains of nitrate of silver in an ounce of water, drained, well washed with pure running water, and allowed to remain in a body of good rain water while another plate is being prepared in the same way. The plate is again drained, after which pour over sufficient of the preservative to easily cover the plate; allow this to remain on the plate about three minutes, occasionally moving backwards and forwards. Again wash, and finally dry.

The preservative is prepared as follows. Take—

Tobacco ...	20 grains
Gum-arabic ...	10 "
Water ...	1 "

The tobacco should be treated with boiling water, and pressed, the decoction allowed to stand till cool, filtered, and in the filtrate dissolve the gum. I use the gum powdered, as it is much more easily dissolved than in its ordinary lumpy state. I find that plates so prepared may be developed either by the simple pyrogallie acid developer, or by the alkaline process. For the former I prepare a solution consisting of—

Pyrogallie acid ...	3.5 grains
Citric acid ...	6 "
Water ..	1 ounce

To develop by the alkaline method I prepare the following solutions:—

No. 1.—Pyrogallie acid ...	6 grains
Water ...	1 ounce
No. 2.—Bromide of potassium... ..	12 grains
Water ...	1 ounce
No. 3.—Carbonate ammonia ...	30 grains
Water ...	1 ounce

Proceed as usual.

From what I have seen of the process, I believe that plates prepared according to the above directions will keep months before exposure, and be about as sensitive as those prepared by the Fothergill process. The negatives are clear and brilliant, with a large amount of detail.

A few trials will probably give a better idea of the process than I can by pen and paper. I therefore leave it in the hands of your readers interested in dry plate photography, wishing them success.

### THE PRODUCTION OF GLASS POSITIVES BY THE POWDER PROCESS.

BY J. B. OBERNETER.\*

To produce a glass positive from a negative in the shortest possible time is often the photographer's wish, and the methods usually employed with the camera, albumen plates, and the collodio-chloride process are more complicated than the manner I am about to describe. The only

\* Photographische Correspondenz.

drawback to my method is that a bright day is necessary for the purpose, sunshine being most favourable to the purpose, for on a dull day the time required for printing is too long.

The theory is, that the iron oxide salts are reduced by light to suboxide, which latter are hygroscopic, while the former are not. Iron salts may be produced, which are just as sensitive to light, for instance, as chloride of silver, but with all these salts there are difficulties in the preparation of the plates, and in the powdering of them; for these reasons I do not employ these questionable materials, and will only describe a very simple and trustworthy method of working.

The best sensitive solution, according to my experience, is the following. I prepare a mixture of—

Citrate of oxide iron	...	...	10 grammes
Citric acid	...	...	5 "
Chloride of iron (concentrated solution)	...	...	2 "
Water	...	...	100 "

The citrate of oxide of iron is, in the first place, very finely powdered, and then the three ingredients are put into a glass flask with the water, and the whole boiled during continual agitation; it is then allowed to stand until all the citrate of iron has dissolved, which generally takes place in about five minutes. After cooling, the solution is filtered through paper, and the liquid is ready for use. It will remain good for several days.

To prepare a plate, the glass surface is first of all carefully cleaned with a little kaolin and water; it is then warmed slightly and coated with the solution, the superfluous liquid being poured back into the bottle; the plate is then dried in a horizontal position upon a stove. After five or ten minutes the film has dried with a mirror-like surface, and whilst still warm it is laid in the printing-frame upon the negative and exposed in the sun for eight or ten minutes, or in the shade for about an hour. After taking the impression from the frame, the plate is breathed upon slightly, when, on careful observation by reflected light, the saturation with moist air of the portions of the film reduced by light can be easily watched. A dusting-brush dipped in graphite, or oxide of iron (rouge), is carefully moved to and fro over the plate, and the picture comes up rapidly, and by blowing upon the film at intervals, with due care, any amount of vigour may be secured.

It is easier to dust a cliché of this kind than one of bichromate solution, such as is used for multiplying negatives. There is here the advantage that portions which, by reason of being too strongly breathed upon, have become too dense, may be lightened again by rubbing, when dry, with a clean brush. One need not apply so much graphite to the plate as in the case of chrome films—indeed, very little need be taken upon the brush. One can easily prevent one's fingers and garments from being soiled in the work.

When the picture has been sufficiently dusted, it is covered with normal collodion, dried, and cut round at the margins. The film is then allowed to float off in a bath of water, which happens in the space of three or four minutes, and it is then reversed, and applied to another glass plate in exactly the same way as when negatives are multiplied.

If reversing of the film is unnecessary, the sensitive solution should be applied, in the first place, in a very thin state, diluting it with three or four times its bulk of water. It is covered, after dusting, with collodion to which a little castor oil has been added. The yellow tint is scarcely observable, and the cliché is then varnished.

A CONVENIENT DARK TENT.

BY T. C. HARRIS.\*

I give below a description of a "dark tent" for out-door work, which is the best thing of the kind I ever saw.

\* Philadelphia Photographer.

It may not be new to many of your readers, but is too good a thing to be lost; neither is the idea an original one with myself. It is simply this: Make a large bag (say three feet square) of three or four thicknesses of orange calico, and for a bottom sew in a piece three by three feet, same thickness. In the centre of this make a small hole, and work the edges like a button-hole. Now get a small rope about twelve feet long, and pass one end through the hole, and tie a knot in it, and the tent is complete: weight, from three to four pounds.

To use: Pick up two rough sticks about four feet long and as large as the finger; tie them together in the middle with the inside end of the cord, to support the top when hung up. The other end of the cord is fastened to a branch or body of a tree, fence corner, or anything else. The sticks are then turned across each other, so as to hold out the top and sides in the shape of a box. It should be about four feet deep and three feet square or larger, hung up so that about a foot of the lower edge will lay on the ground. The bath, chemicals, &c., are placed inside, on the ground, against the back-wall, and the front side is lifted to get under.

In moving from place to place, the tent can be rolled up in a small, compact bundle, and tied with the rope. I find four-thick orange calico to be ample, and will admit plenty of light to work by, but not fog the plates. A little window of orange glass, four by four inches, can be added, but is unnecessary. One of these tents can be made by anyone, and is really worth a dozen of the unwieldy things sold by stock-dealers.

HINTS ON LIGHTING.

BY R. J. CHUTE.\*

This is an old subject; it has been treated over and over again, but so long as our art is practised, and there are those who are striving to learn, its discussion will be not only necessary, but most welcome to many who are seeking for improvement.

The construction and situation of the light is of such importance that it should be the first consideration in erecting or refitting a gallery. It is the basis of all success or failure, and those not thoroughly versed in this direction will do well to look to it for the cause of some of the shortcomings they experience, and which they are endeavouring, in vain, to overcome. I would advise no one to be influenced by this or that theorist as to the arrangement of a light, but rather investigate the causes that have given the greatest success in the photographic art. H. P. Robinson says:—"Some men succeed in spite of difficulties." This we all know to be true, and also that hundreds fail on account of difficulties. Now, in erecting a gallery, the better the light can be applied to the work the less difficulties there will be to overcome, and the more uniformly successful will be the work done under it.

I do not propose, at this time, to give any directions or specifications in reference to the construction of a skylight,

\* Philadelphia Photographer.

but simply to suggest the importance of this department of the studio, and to express my belief that the greatest fault that is general in photographic skylights is expressed in two short words—viz., too high. I know of no one who has ever achieved great success under a high light unless it was correspondingly large; while it will be found that those who have won both fame and fortune have done it under comparatively low lights. Burnett, in his "Practical Hints on Light and Shade in Printing," in reference to "the means by which the painter works," says: "That there is an art in the management and disposition of those means will be easily granted, and it is equally certain that this art is to be acquired by a careful examination of the works of those who have excelled in it." That the above is as applicable to photography as to painting, all will readily admit. The means by which we work, and our success in their management and disposition, determine the quality of art culture there is in us. And as light and shade, exclusively, give all the varied effects we strive for, it is of the utmost importance that we should find, if possible, the best means for using these agents of our will that assume form and place at our bidding, giving the semblance of something tangible in all the beautiful gradations which we see in the best works produced by our art. To do this we have not only to study the works of those who have excelled, but, as far as possible, the means by which they achieved success.

The use of a top and side light combine I have generally been recommended, and probably nine-tenths of the lights in use are so constructed. The side-light is useful and sometimes necessary, but is subject to such abuse that its general utility may be questioned. A low top-light produces every effect desired in ordinary portraiture, and even those not skilled in the art of lighting cannot then easily go astray.

There is a disposition among many to use too much side-light. The effect is very bad in most cases. The beauty of the eyes is seriously impaired by the reflected side-light; the natural shadows of the face are destroyed, and the features either appear distorted, or are weak and insipid. That important feature, the mouth, around which plays so much of sentiment, life, and beauty, loses nearly all its charms under this treatment. The delicate shadows that delineate the exquisite curves and lines of character and expression are quite destroyed; the upper lip is lighted almost equally with the lower, the shadow under the latter is wanting, and if the light on the face is softened to any extent, the whole becomes as near a blank as anything can possibly be and still have form.

Now, the best workers of to-day use side-light very sparingly, and those who have not the fullest confidence in their abilities or knowledge, or have failed to satisfy themselves in their own work, should study the difference between their own and the work of some of those who have succeeded best, and ascertain, if possible, wherein the difference lies.

When full figures were in demand, a fair proportion of side-light was rather necessary, in order that the subject should be properly lighted; but then the effect was considered in reference to the whole form, the face, of course, being the most prominent, but still subject, in a great degree, to other and less important parts. But in these days, when the face is the picture, and the most exquisite modelling is required to give it truthfulness and beauty, success depends either upon the most consummate skill, or vary favourable conditions.

#### HOW TO AVOID UNNECESSARY WASTE OF SILVER.\*

The developings and first washings of the negative are rich in silver, most of which can be saved by using proper means and care. The plan recommended in Anderson's

\* Philadelphia Photographer.

"Skylight and Dark-room" is about the best, but some simpler method will answer very well. Any large vessel into which you can run the developings and first washings, where they can remain undisturbed long enough to settle, will answer the purpose. The iron in the developer is sufficient to precipitate all the silver held in solution, but it settles slowly. When the vessel is full let it stand a day or two, and then decant what you can; filter the remaining liquid through a cloth or paper filter, and when you have obtained sufficient precipitate to make it pay, you can reconvert it to a workable condition by simply submitting the precipitate to the action of muriatic acid, which will dissolve out the ferro-sulphate, and leave a residuum which is pure silver, requiring only to be thoroughly washed and then dissolved in diluted nitric acid; the acid may be driven off by evaporation, or neutralized, when the silver solution becomes ready for use.

In fixing the negative, some operators prefer to use cyanide of potassium, but hyposulphite of soda is most generally used; in either case a shallow dish or tray large enough to lay a number of negatives in, face up, with solution enough to well cover the same, is the most convenient and economical. By fixing in this manner, the solution becomes rich in silver, all of which can be recovered by the galvanic process; but if you do not like to fuss with a battery and are in no hurry, you can immerse a piece of copper or a copper plate in the hypo or cyanide solution, three or four inches square, and let it remain; the pure metallic silver will be deposited upon the surface of the plate, and when desirable to do so you can scale off the silver, and reduce it with nitric acid, evaporate, or neutralize, and the silver solution is ready for use.

Of course I am aware that there are several other ways of recovering silver from the solutions above mentioned; but the plan here recommended is the most easily managed by the majority of operators. The chlorides, carbonates, &c., are also easily managed; but the sulphurets, &c., require brains and other conveniences, which I do not propose to furnish. A great deal of silver might be retained in a workable condition by using a little forethought. For instance, suppose you obtain a large open-mouth bottle, or other suitable vessel, and place it in some convenient spot. Now, when you rinse out your negative bath holder, pour the first rinsings into the bottle; and when you have done with a filter, just drop it, while wet, into the same bottle. Do the same with blotting-papers, sponges, and, in fact, everything which becomes saturated with the negative solution. By constant additions the contents of the bottle gain volume and strength, and an occasional stirring will reduce the whole to a pulpy mass, which should be strained, and squeezed as dry as possible, and then the weak solution thus obtained can be strengthened with new silver, or by boiling down, and is ready for use either to renew an old, or to make a new, bath.

By making the contents of the slop-bottle tolerably strong of nitric acid, the silver contained in old dry filters, clippings, &c., can be reduced and utilized.

The advantage of some simple plan of avoiding waste must be obvious to any one who will stop to think of the foolishness of "going around Robin Hood's barn" to save a mere fraction of the silver which he has made into a conglomeration which could be avoided with less trouble.

#### THE PREPARATION OF ALBUMENIZED PAPER.

In the *Photographische Correspondenz*, M. J. Homolatsch describes his plan of albumenizing paper, which he has practised for many years with success; he simply floats his paper on albumen, and does not resort to the plan of rolling, which, he says, gives a borrowed gloss that disappears when the paper is washed and toned and fixed. Thirty ounces of fresh white of egg are, according to the amount of water in the eggs, mixed with ten to twelve ounces of water, and forty grains of chloride of ammonium and

thirty drops of glacial acetic acid are added; according as the tint of the albumen is light or dark, so a few drops of aniline red are added, and the whole beaten to snow. In a few hours the froth becomes liquid again, and the albumen is put into a bottle to ferment, when the fibrine becomes deposited. The aniline red is added merely for the purpose of neutralising the green tint of the albumen; care must be exercised not to add too much colouring matter, as the prints will then appear rough and mealy.

Before the albumenizing is begun the liquid is filtered through thick linen and filter paper, and is then allowed to remain for an hour, for the air-bubbles to become separated and rise to the top, when they are skimmed off with a bit of blotting-paper.

The paper is placed, face downwards, upon the albumen, and allowed to float until it is perfectly flat. Two corners, which have been bent up, are seized, and the sheet carefully raised and placed to dry. It is now ready, and the drying is finished under a press. It is quite free from smell, and is best used after a few days, when the film has become hard. Cutting and rolling are unnecessary, and are only undertaken when the paper is to be disposed of commercially, any gloss the paper receives in this way disappearing after it has once been put into water. When the liquid becomes thickened after use, it is diluted with an ounce of distilled water containing a grain of chloride of ammonium in solution.

### Correspondence.

#### FADING OF ALBUMENIZED PRINTS, AND PERMANENCY OF PLAIN PAPER.

DEAR SIR,—The fading of our photographic prints is one of the prominent subjects of the day. Like many of my brother amateurs, I have been annoyed, but only occasionally, by the loss of colour and brilliancy in some of my best specimens. After careful observation and experiments, I am decidedly of opinion that prints on albumenized papers fade, when those on plain salted do not. The subject is an interesting one, and, by comparing notes, something satisfactory may be arrived at.

I may state that I have not had a single case of fading when the toning has been done in the sulphocyanide bath, as given in the PHOTOGRAPHIC NEWS in 1867.—Yours, &c.,  
AN AMATEUR.

#### SENSITIZED GELATINO PELLICLE.

SIR,—I hope others will give their experiences with Kennett's pellicle. His paper was so positive as to the certainty of his gelatine emulsion that I considered it my duty to try it. The following were the results.

I coated some plates, and put them to set on a levelled piece of glass, then dried by heat. I found them sensitive enough, and got an image by reflected light, but next to nothing by transmitted light. This doubtless would have been all right by after-development; but what I could not get over was the tendency of the film to blister. When I attempted to wash it, a coating of opaque network came over it, and then it slipped from the glass in a rotten state. I tried several plates, but all were alike. I took every care and followed his instructions most carefully.

When I first saw the instructions, my heart failed me on account of the numerous alterations in ink and extra instructions written on the back. I also thought that greater care was requisite in packing the little box of paper—one thin and scanty covering of white paper.

Mr. Joshua King talks of the tendency of gelatine emulsion to blister in a most unaccountable way. It appears to me that unless the film is firm and stable, the process is useless.—Yours faithfully,  
W. J. C. M.

#### MR. WOODBURY'S PHOTO-MECHANICAL PRINTING PROCESS.

SIR,—In your last issue you printed specification of patent taken out by me for improvements in photo-mechanical printing, to which you preface the remark (true in one sense) that this invention was only provisionally protected. As this would cause your readers to suppose that the patent had thus become public property, I beg to state that such is not the case; a "de novo" patent having been applied for before the time at which this one could be made public causes it to be legally valid.

To prevent any misunderstanding, I beg you will publish this statement,  
WALTER B. WOODBURY.

Greenhithe, July 13th.

#### COLOURED GLASS, ETC.

DEAR SIR,—Finding Mr. Nicol's habit of quibbling incorrigible, and only likely to tend to interminable disputation, and that he condescends to pervert my meaning, I should not have considered further necessary; but as those of your readers who may not have had an opportunity of considering the question might, from the tone he assumes, think that his words had weight, or are, in fact, any more than mere clamor, I point to the letter of Dr. Vogel, who cautions that the theory to be obtained from the examination of stained glass will not hold good as regards the colours of the spectrum. One moment's consideration will prove this to be only a reasonable conclusion, as the latter, always emanating from the same source, must, under similar conditions, prove identical; whereas stains, dyes, and pigments, derived from so many various substances, each having its own peculiarities, can be subject only to their own laws. Blue has been used to lower the tone of the colour of the light admitted into the so-called dark-room with beneficial effect, but, of course, there must be sufficient to bear the dilution. A blue varnish might be used, and prove inexpensive; in any case, a little colour is required.

My caution respecting the measures was based upon experience gathered whilst making inquiries concerning them. Should it be considered obtrusive or unnecessary, I must plead that Mr. Nicol's example has proved infectious. As regards the weight of water, I reiterate, that the quantity of water calculated as to the old measure is correct; but provided that the twenty-ounce pint be used, the denomination of the product will, of course, be different.

I consider this discussion is now closed.

The hot weather we have experienced points out the necessity of some regulation for preserving the health of the working portion of the photographic community, and I was much pleased to read the very valuable papers of Dr. H. Napias, as also the remarks concerning the health of photographers in the PHOTOGRAPHIC NEWS of the 10th inst., which are virtually identical with what I have written on the same subject.

In my next letter I shall resume the subject of the interior of the dark room.—Yours truly,  
JAMES MARTIN.

5, Clarence Place, Ilfracombe, July 14th.

#### THE HEALTH OF PHOTOGRAPHERS.

SIR,—In an article on health in connection with photography, you say that the dark-room window cannot be opened between the developing of each plate when much work has to be done. This is a mistake, as, when the baths are provided with proper covers (mine are attached to the dippers, and there is, therefore, no loss of time in using them), the window may be thrown open immediately the plate is developed, and the air of the room gets well changed while washing and fixing. This does not interfere with a succession of plates as rapid as can be used by the posing operator.

Another point you mention is, the necessity of a mid-day meal; which, you say, is only taken by stealth in some establishments.

I trust that such houses are exceptions. I never knew of one where so little consideration was shown to the employees.—I am, yours obediently, W. E. DEBENHAM.

158, Regent Street, July 14th.

[We referred to some establishments in which two operators were engaged in one dark-room, in which it was not possible to open the window much without interfering with one or the other. Where one operator has control of the room, he can, and, doubtless will, open the windows between each plate.—Ed.]

## Talk in the Studio.

**IMPERIAL RECOGNITION OF PHOTOGRAPHY.**—English photographers, it seems, can compete satisfactorily with Continental artists in royal portraiture. The following letter has been forwarded to Lord Torrington, relating to some very admirable portraits and groups of the Emperor of Russia and his daughter, by Messrs. Downey, of London and Newcastle-on-Tyne:—"MY LORD,—I am instructed by His Imperial Majesty, the Emperor of Russia, to acknowledge the receipt of the photographs which were executed by order of Her Majesty the Queen, and forwarded by Messrs. Downey through your Lordship; and I am desired to express His Majesty's high approbation of the same.—I have the honour to be, my lord, your lordship's obedient servant, BRUNNOW."

**BIRDS, NOT BANDS.**—At the annual meeting of the National Photographic Association of America, just opened at Chicago, we learn that a feature of the exhibition would be the substitution for the band, which on such occasions makes night hideous and day unendurable, of a large lot of singing birds, with their eyes hid in the boughs and flowers used for adorning the hall. The exhibition was to open on the 14th of July, and continue until the 18th.

**FINED FOR PUBLISHING A PHOTOGRAPH.**—M. Apert, a photographer in Paris, has just been sentenced to a fine of 100 francs for publishing without authority a photograph representing the majority of the Prince Imperial.

**NEW METHOD OF COLOURING METALS.**—Metals may be coloured quickly and cheaply by forming on their surface a coating of a thin film of a sulphide. In five minutes brass articles may be coated with any colour, varying from gold to copper red, then to earmino, dark red, and from light aniline blue to a blue-white, like sulphide of lead, and at last a reddish white, according to the thickness of the coat, which depends on the length of time the metal remains in the solution used. The colours possess a very good lustre, and if the articles to be coloured have been thoroughly cleaned by means of acids and alkalis, they adhere so firmly that they may be operated upon by the polishing steel. To prepare the solution, dissolve  $\frac{1}{2}$  ounces of hyposulphite of soda in 1 pound of water, and add  $\frac{1}{2}$  ounces of acetate of lead dissolved in  $\frac{1}{2}$  a pound of water. When this clear solution is heated to from 190 to 210 degrees Fah., it decomposes slowly, and precipitates sulphide of lead in brown flakes. If metal is now present, a part of the sulphide of lead is deposited thereon, and, according to the thickness of the deposited sulphide of lead, the above colours are produced. To produce an even colouring the articles must be evenly heated. Iron treated with this solution takes a steel-blue colour; zinc, a brown colour; in the case of copper objects, the first gold colour does not appear; lead and zinc are entirely indifferent. If, instead of the acetate of lead, an equal weight of sulphuric acid is added to the hyposulphite of soda, and the process carried on as before, the brass is covered with a very beautiful red, which is followed by a green (which is not in the first-mentioned scale of colours), and changes finally to a splendid brown, with green and red iris-glitter. This last is a very durable coating, and may find special attention in manufactures, especially as some of the others are not very permanent. Very beautiful marble designs can be produced by using a lead solution thickened with gum tragacanth, on brass which has been heated to 210 degrees Fah., and is afterwards treated by the usual solution of sulphide of lead. The solution may be used several times.—Iron,

## To Correspondents.

**H. H. K.**—There are a great many methods of photographing on wood for the purposes of the engraver, all more or less efficient. It would be impossible to describe any of them in detail in the column apportioned to answering correspondents; but you will find one of the best processes described in full in our issue for June 3rd, 1870. The process there described does not leave any film of collodion or other substance in the wood. Should you not succeed with that, write again.

**AMATEUR.**—Silver is usually sold by troy weight.

**F. H. W. B.**—Pyrogallic acid when kept in aqueous solution is apt to spoil, and lose developing power. You will best ascertain by trying the stock you have; but when it has turned a dark brown there is not much hope. You need not, however, be in any difficulty, for your ordinary iron solution may be used for intensifying. Many of the ablest photographers simply add a few drops of silver solution to the developer, and intensify with that. If it readily decompose when the silver is added, add a little acetic acid as well, which will check the decomposition.

**BUSY BEE.**—We cannot tell you whether there are any of the panoramic cameras in use at the present time. Mr. Johnson's was undoubtedly the best, and produced some very fine results. We do not remember certainly who is the agent at the present time; but you would learn of the Autotype Company, Rathbone Place.

**POPE.**—For mounting prints in an album we should use a thick solution of india rubber, applying it only to the edges. The prints, if properly managed, will be as flat and firm as if mounted by pasting all over. They will not cockle, and can be removed at any time without injury if it be desired to make a change in the album.

**T. H. REDIN.**—Thanks. It is tolerably clear, we think, that the depth in the paper of the sensitive impression is much dependent upon the amount of soaking which the paper received in the different stages of preparation. If, in albumenizing, the paper be floated sufficiently long, the chloride present will be absorbed into the texture of the paper. Such paper, when floated on the silver bath, will readily form chloride of silver in the texture of the paper, and the image will be found there after printing. The conditions of brilliancy depend much on keeping the image on the surface; hence paper albumenized by rapid floating—or, rather, simply drawing the paper over the albumen solution—will generally yield the most brilliant prints. Long floating on the silver bath will also tend to give an image in the paper. If you print with the back of the albumenized paper in contact with the negative, you will obtain an image right through the texture of the paper.

**VINDEX.**—The ownership of the copyright depends on two or three things. If a photographer procure a model or sitter to sit to him for his (the photographer's) own purpose, then the copyright rests in the photographer without any agreement; but if a sitter come in the ordinary way of business for a portrait, then it will be necessary to obtain an agreement in writing in order to secure the copyright to the photographer, and no registering will secure the copyright without such written agreement.

**HENRY EDWARD.**—We cannot devote further space to the subject. We shall hear no more of the *soi-disant* "M.D.," whose trick was so easily and completely exposed. You should remember the remark of a late American President: "It is no use wasting ammunition upon dead ducks."

**HOPE.**—Pinholes in negatives may proceed from many causes, excess of iodide of silver being the most common. It is possible to have a new bath over-iodized. Besides this cause, turbidity and floating particles in the nitrate bath; a turbid developer; collodion not perfectly settled, and similar causes, will cause pinholes; but, without tracing one cause after another, we cannot guess which is in operation in your case. To stop them out in the negative, use a fine, short-haired sable pencil and a little cobalt blue.

**F. T. D.**—The yellow spots on the two cards and cabinet so closely resemble those produced by the bronze powder used in printing, that we should have no hesitation in assigning them to that cause. Have you any examples mounted on cards in which the gilt printing is not employed? The soaking all night which you describe would be better avoided, as it tends to set up a decomposition in the sizing matter of the paper. 2. There is additional chance of permanency gained by the use of the ammonia. 3. The tear-drops we should be disposed to attribute to splashes of silver in the plate from closing the shutter of the dark-slide hastily.

**G. AIMEE.**—We do not know the precise address of Dr. Napier. Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### WHERE TO GO WITH THE CAMERA.

Where to go with the Camera.—Photographers should lose no time in making up their minds where to go with the camera, for the summer will soon be on the wane, and we shall have September and October upon us before six weeks are over. Shall it be the chalk hills and green woods of Kent, about Boxley, or along the grassy banks of the Medway, by Maidstone and Watlingbury, or the shady lanes and apple orchards of Devonshire, or the rocky headlands of Cornwall? If the sea-scapes here are too wild and lonesome to please, and foliage and picturesque cottages are sought for, to relieve sea and sky, there are North Wales and North Devon which will be more to one's taste. The pastoral scenes of Derbyshire, the lakes of Cumberland and Westmorland, and the stretches of undulating country in Yorkshire, have their admirers; while the border counties of Wales well repay exploration by those who love quaint little towns, wooded slopes, and lazy streams flowing past green landscapes, and shady nooks tapestried with ferns and flowers. Scotland, with its broad moorlands and picturesque glens, its placid lochs and silver-grey peaks, will draw many over the border; and, if it were not for the lengthy hotel bills one has to pay occasionally, it would be the most favourite tour of all. *Point d'argent, point de Suisse*, is an old and true saying; but *Ecosse* might very well be substituted for the last word now-a-days.

To those who go abroad, there is more choice of scenery, although travelling on the Continent, as many will agree with us, is not pleasure unalloyed. If unacquainted with the language of the country one visits, it is always necessary to keep to big hotels and frequented districts: and, besides being always in an atmosphere of Paris, Berlin, or London, according to the nationality of the numerous visitors around, you are compelled to pay dearly for everything you have. You need not, however, be a very learned linguist to make your way, for a knowledge of practical matters is all that is necessary. Every year the beauty spots of the Continent are brought more nearly within our grasp, and centres such as Paris, Cologne, Bale, &c., may be reached very speedily, whence one's destination may be afterwards be easily attained. Switzerland, the Tyrol, the Rhine, the Pyrenees (although, with the Carlist war raging just now, it is unlikely many will like to risk their lives in that part of the world), and the pretty forest districts of Mid Germany are all of them within eight and forty hours of England. Even Norway may be reached overland (in great measure), through Cologne, in three days, as rapidly, therefore, as the journey may be done across the North Sea, and with much more comfort to those who are not sailors. Switzerland and the Tyrol can be attained by the new Luxemburg line to Bale, in shorter time and with less fatigue than by way of Paris, no change of carriage being necessary all the way from Ostend. Unfortunately, the journey is at present an expensive one, costing a five-pound note, for the quick trains are only first-class. Tourists should bear in mind that if they desire to travel economically they must beware of the more popular districts. People go to Lucerne, Interlaken, Chamonnix, the Rigi, Geneva, and other places, simply because they hear of others going; but there are spots quite as charming and grand as these, both in Switzerland and the Tyrol, where one is not always moving in a crowd of tourists, and where you may live in moderation. In some parts of the Grisons, in Appenzel, in the Vorder Rhein Valley, and about Chur and Wallenstadt, there are districts to be visited which possess all the finest characteristics of Swiss scenery;

and if you but cross the grand Stelvio Pass, the highest, and, we think, the grandest, in Europe, there is the Tyrol beyond you, where you may wander at will and never be called upon to pay more than half the amount for bed and breakfast than the Lucerne and Interlaken inn-keepers ask you. There is snow-hooded Ortler Spitz within stone's throw, and the magnificent Crystal Glaeier sweeps down to the road side, while from the head of the pass, which is a thousand feet above the line of permanent snow, hundreds of magnificent peaks are to be seen. The Finstermunz Pass, the tiny lakes of Graun and Reschen, the beautiful Oetzthal Glacier, may all be visited in a week, only the traveller must be prepared to rough it a little, and make shift to live for a while on omelettes, trout, and good red wine, for little else is sometimes obtainable. The valleys of the Engadine on the confines of Switzerland, Italy, and the Tyrol, are becoming every year more fashionable; and as the Prince of Wales intends spending a few weeks there this summer—at St. Moritz—the claims of modest travellers will cease to be considered. To those who prefer the depiction of architecture to that of mountain and valley, there are many quaint towns to be visited nearer home than Nuremberg and Prague, which are oftentimes quoted as full of models for the photographer. He will be very clever, however, if he is able to produce pictures for business purposes, and compete with local artists with all their advantages. There are Antwerp, Ghent, and Bruges, and other towns in Flanders and Belgium where time may be profitably spent; or, again, the old cities of Normandy and Brittany, with their old churches and cathedrals, may be visited. One always prizes a picture taken oneself more than a print which is purchased, for, besides the interest otherwise attaching to it, the fact that it has been secured from a point of view with which you are familiar often makes all the difference. Besides, when one has had a pleasant holiday ramble, what can be more pleasant afterwards than to look over pictures taken by the way, each of which recalls to mind some pleasing reminiscence, or some amusing story?

#### FRENCH CORRESPONDENCE.

IN a letter dated the 13th July, the committee of the French Benevolent Association for Photographers inform me that they have unanimously decided to forward the following letter to their medical adviser, Dr. Napias:—  
“DEAR DOCTOR,—We are charged by the executive committee, in the name of the Photographers' Benevolent Association, to inform you that an unanimous vote of thanks has been given you for the valuable advice contained in your paper published in our organ, the *Moniteur de la Photographie*, upon the sanitary aspect of our studios, and upon the means to be adopted in the case of accidents taking place among us. With our most sympathetic thanks, and in the hope that you will continue a work so well begun, we beg you will receive our heartfelt conviction that you will not cease to have the good of our society at heart, and we greet you, happy and proud to be numbered amongst your friends.

(Signed on behalf of the committee)

“E. FONTENELLE, *President*.

“BERTHOLST, *Secretary*.”

I am sure that the readers of the PHOTOGRAPHIC NEWS who have become acquainted with Dr. Napias' work will read this letter with pleasure, and agree with the sentiments expressed therein.

Under the title of *L'Achromatisme Chimique*, M. Prazmoski has just presented to the Academy of Sciences a note bearing importantly upon photographic optics. Charged by M. Janssen with the construction of an apparatus of considerable dimensions for photographing the transit of Venus across the sun's disc, M. Prazmoski occupied

himself first of all with the conditions of optic achromatism to be given to the whole of the optic system. The principles which govern the manufacture of photographic lenses cannot be applied to instruments destined for the depiction of astronomic bodies. An optical lens is one which unites at the point brightest to the eye the luminous rays and those which exercise the most powerful actinic action. In this way is obtained a mean result which gives precision to the optical image without the photographic image having all the sharpness possible. The coincidence of the two foci facilitates the operation of focussing, and gives to the photographic image a certain softness, very desirable in portraiture, but not so in photo-astronomy.

It is known that to obtain the most satisfactory achromatism to the eye, one should not attempt to unite the extreme colours of the spectrum, but only those that affect the most powerfully the organ of vision; in photographic achromatism it is only necessary to take into account that portion of the spectrum where the chemical action is most strongly marked. The range of the chemical spectrum is well determined, but it varies according to the nature of the bodies traversed by the light. It is more especially to this point that MM. Janssen and Prazmowski call attention. They have executed some photographs of the spectrum by means of prisms of flint and crown, which are to be employed in the construction of the lens and eyepiece, or rather of the apparatus for enlarging the image given by the lens; and these pictures prove that the most powerful action is produced at that part of the spectrum comprised between the lines G and H. Beyond H the action is less sensitive, and rapidly ceases. Between F and G the rays are very sensitive, but much less energetic than between G and H. The most perfect photographic achromatism, according to M. Prazmowski, results from the union into one focus of the rays G and H, encroaching a little upon the interval between F to G.

After these experiments, it remains to find the curvature of the lenses. M. Prazmowski has followed the principles laid down by the eminent mathematician Brot. According to him, the essential condition to obtain a perfect lens is the stability of the axial and lateral achromatism, and this stability is only assured by central contact between the two glasses that compose the lens. It is perfect when the two interior surfaces are in contact throughout their whole surface, and this condition can be satisfied by exercising a proper selection in the materials employed.

M. Prazmowski has, therefore, commenced to study with care the properties of the crown and flint glasses which he proposes to employ, and he has calculated, by means of trigonometry, the curvature of the rays. In his lens the marginal rays are absolutely achromatic. The achromatization of the centre is not so perfect, but the small error existing is inappreciable.

Photography, which should, now-a-days, form part of education, at any rate in polytechnic schools, if not at all, is only taught in France, just now, at special institutions, such as the *Ecole des Mines*, *Ecole d'Application du Genie Maritime*, *Ecole Central des Arts et Manufactures*, and at the *Ecole des Pont et Chaussées*. When I say taught, I go, perhaps, a little too far, for, in the first three establishments mentioned, the instruction is confined to a short course of lectures. It is different, however, at the *Ecole des Pont et Chaussées*, where our art is practically demonstrated and theoretically explained by M. Davaune. This gentleman is provided with everything necessary for teaching photography in a most complete manner, and his great experience, as also the zeal that he feels in the matter, make him fully qualified for the post.

The course of lectures given by M. Davaune at the *Ecole des Ponts et Chaussées* has just been published in a pamphlet of fifty-four pages. In this limited space we have one of the most complete and useful operating manuals, which

will, no doubt, enjoy a large circulation. The author first gives a concise and very impartial history of photography, and then proceeds to detail the manipulations necessary in the production of negative and positive impressions. The first part of these divisions contains four chapters devoted to the wet and dry collodion processes, collodio-albumen, collodio-tannin, waxed paper, and other processes; and in the second part the author treats, first of all, of positives, and silver salts, and residues; and then passes to printing without salts of silver, but by means of bichromated gelatine, the carbon process, Woodbury process, helio-engraving, photo-lithography, and enamel photography.

M. Davaune devotes, moreover, two chapters to the employment of iron salts and bitumen of Judea, and terminates with a formula which may be taken as the resumé of his work. The two formulæ which the professor has chosen among those published of the wet collodion process are the following:—

*First Formulæ—Normal Collodion.*

Rectified sulphuric ether	...	650 cub. cents.
Pyroxiline	...	10 to 12 grammes
Alcohol at 40°	...	added by degrees, 300 cub. cents.

*Iodizing Liquid.*

Absolute alcohol	...	250 cub. cents.
Iodide of ammonium	...	10 grammes
Iodide of cadmium	...	10 "
Bromide of cadmium	...	10 "

Filtered through paper.

Ninety cub. centimetres of normal collodion are taken, and to this are added ten to twelve cub. centimetres of the iodizer, and a tiny flake of iodine, to give the mixture the colour of Madeira.

*Second Formulæ—Collodion.*

Rectified sulphuric ether	...	300 cub. cents.
Alcohol at 40°	...	200 "
Pyroxiline	...	5 to 6 grammes
Iodide of potassium	...	1 granme
Iodide of ammonium	...	1.75 "
Iodide of cadmium	...	1.75 "
Bromide of potassium	...	0.25 "
Bromide of ammonium	...	0.50 "
Bromide of cadmium	...	0.50 "

The iodides and bromides should be finally ground before being added to the collodion. M. Davaune adopts a seven per cent. dipping bath, and develops with an iron solution thus made up:—

Double sulphate of iron and ammonia	50 grammes
Ordinary acetic acid	50 cub. cents.
Alcohol at 36°	50 "
Ordinary water	1000 "

In the ten per cent. silver bath for positives, M. Davaune puts a few drops of a solution of carbonate of soda. Into the gold toning bath of one per mille strength, he puts five grammes of French chalk.

For mounting—a very important part of photography, as everybody knows—he uses—

Water	...	500 cub. cents.
White glue	...	12 to 15 grammes.

After boiling for ten minutes, thirty grammes of starch are added, diluted in a little water, which is boiled and strained through a muslin sieve.

In conclusion, I may repeat that, as every one might expect, M. Davaune's modest looking volume is one of the most useful and complete manuals that have hitherto been published on the subject of photography.

ERNEST LACAN.

## HOW TO MAKE A POCKET CAMERA.

BY W. J. LANCASTER.\*

DRY plates may be prepared in so many different ways, that one is at a loss to know which process to describe, and which to dispense with. It is an astonishing fact that one process works admirably with one person, and with another, working apparently similar, it gives nothing but foggy pictures—pictures without any depth, negatives with no detail. It is from this fact that I have determined to give some half-dozen processes, leaving the amateur to choose that process most suitable to his taste, and to work at that one until he shall obtain good and lasting results. I have known so many amateurs who try every new process, and yet never succeed with one, although they may have a cupboard full of pure chemicals, which, with careful attention, would produce charming results, that I must beg of my readers to take one process and stick to it. One of the simplest processes with which I am acquainted is the coffee process. The method of working is the following:—

First, provide yourself with some patent plate glasses, or some polished sheet of good quality. Clean them well. This is very important, and may be best done by rubbing the glasses with methylated spirits of wine upon a piece of cotton-wool. Allow the spirits to evaporate, and then polish well with a good chamois leather. Secondly, procure some good bromo-iodized collodion, to which may be added, if necessary, a small quantity of a solution of bromide of cadmium; it should be a firm collodion, one that will not give a reticulated appearance to the plate; neither must it be too thin. Care must be taken to obtain a collodion which will not peel off the plates. After collodionizing the plate, it must then be lowered into bath, the solution in which should contain about 35 to 40 grains of silver per ounce; then carefully, but without any stoppage half-way, lift plate out of bath and examine its surface, plunge into bath again, examine plate about once every half minute, and finally, after leaving plate in bath from three to five minutes, take it out and swill it well with distilled water. This may be done by immersion in a dish, or by pouring the distilled water out of a jug into the plate. In the latter case quickness is an essential to obtaining good dry plates. The plate is then coated with the following solution:—Coffee 2 parts, gum 1 part, sugar 1 part, hot distilled water 20 parts. This should be made about one hour before using, and should be filtered. The solution may be poured over twice, and the plate placed in a drying frame, or reared up in a box or covered space to prevent dust adhering to its surface. The plate may then be backed, or a piece of black cardboard gummed on to back to prevent light passing through plate to opposite plate when in dark slide. I usually place a piece of thin cardboard of a dead black appearance between two plates in dark slide, and find it answer in most cases quite as well as backing. The plates require from three to five times the exposure of a wet plate. The development of all dry plates is so similar, that I intend leaving instructions for development till the end of paper. In the preparation of dry plates by the following process, the same precautions are necessary as for coffee plates. In fact, the processes differ only in the composition of the preservative applied after plates have been taken out of bath and well swilled. The tea process is similar to the coffee, the preservative being composed of 1 ounce of best black tea and 16 ounces of hot distilled water. These plates do not keep so long as the coffee plates. They require development within two days after exposure to bring out their best results. Care must be taken not to allow sugar or gum of any kind to be mixed with the tea. The tannin process requires a similar collodion and bath as the coffee process. The plates,

after being well washed, are coated with the following solution:—Distilled water 36 parts, tannin 1 part. The tannin solution should remain on the plate from thirty to forty seconds. The gelatine process differs slightly from the processes mentioned, the plates requiring a much better washing, to do which they should be placed in dishes filled with distilled water; they may be also changed from one dish to another, so as to entirely remove all traces of silver, after which coat the plate with the following solution:—Distilled water 100 parts, best gelatine 1 part, alcohol 10 parts. This solution should be heated and poured on the plate while hot. The gelatine must be dissolved in boiling water. The solution must then be filtered before cooling.

The hot water process is a very simple one, and consists of an application of a solution of albumen in water upon the plate after it has been well washed. The plate coated with the albumen must then be placed in a dish of hot distilled water for thirty to forty seconds, afterwards allowing it to dry in a box or other place free from dust.

The collodio-bromide process consists of the application of an emulsion containing the collodion and silver mixed in proper proportions as per following formulæ:—Alcohol 5 ounces, ether 10 ounces, pyroxyline 2 drachms, bromide of ammonia 1 drachm, bromide of cadmium 2 drachms; to this must be added the following solution: alcohol 7 ounces, nitrate of silver  $\frac{3}{4}$  ounce. This solution must be boiled to dissolve the nitrate of silver. The alcohol should be added to the silver, and decanted at intervals after being boiled. The whole should then be allowed to cool, and mixed with the collodion of the formulæ given above. There is no necessity to make so much of the solution as given above, but the solution will keep, and there is as much trouble in making a small quantity as there is in a larger quantity. I should recommend that it should be kept in three or four small stoppered bottles; it is also advisable to keep a small stock of solution No. 2 to add to the emulsion a short time before using. After pouring the emulsion on the plate, it must be then washed well with distilled water. Ordinary water is a source of many failures, and after washing the plate, pour on to coated surface a solution of tannin of the following formulæ:—Tannin 1 drachm, alcohol 1 drachm, distilled water 4 ounces. The plates must then be carefully dried, and may have a piece of black paper gummed on their backs, or be coated with a solution of asphalté.

The development of dry plates, most preferable, is the alkaline method, which consists essentially of a solution of ammonia and bromide of potassium with pyrogallie acid. Make a solution of distilled water 1 ounce, liquid ammonia 1 drachm. Put it into a stoppered bottle, and label it "Am." Then into another bottle put 1 ounce of distilled water, and bromide of potassium 3 grains; into a large stoppered or cork bottle put distilled water 10 ounces, pyrogallie acid 1 drachm. The bottle containing bromide of potassium to be labelled "B.P.," and the bottle containing pyrogallie acid to be labelled "Developing Solution." After the plates are removed from the dark slides a solution of spirits of wine and water, about two of the former to one of the latter, should be poured over plate; or, what is far preferable, is to have a dish containing the mixed spirits and water, then to place the plate quickly into this dish, allow it to remain twenty seconds, then take out and wash well under the tap until all greasy marks disappear. The developing solution should then be poured on plate as quickly as possible, and should consist of 2 drachms of developing solution, 3 drops of ammonia solution, and 2 drops of B. P. solution. The drops from small bottles should be put into a glass measure, and the pyrogallie poured on them, thereby insuring a perfect mixture; it should then be flooded over plate, and great attention must now be paid to appearance of plate. If the picture flashes out instantaneously, then pour developing solution back into measure, and add

\* Concluded from page 315.

2 drops of B. P. solution. If, on the other hand, the picture appears flat and very slow in development, add 1 drop of ammonia solution. The picture may be worked up to any density by the addition of drops of ammonia solution, but I should suggest that amateurs should work with a weak solution until they can thoroughly master the development. I have many times developed plates entirely with the above developer, and with great success; but one must have recourse to the addition of nitrate of silver to the development for obtaining intensity, where the alkaline fails to give the amount required. To do this the plate must be well swilled, and then have a solution of citric acid poured over its surface, then swilled, and ordinary pyrogallie acid and silver may be applied to finish the development. The fixing solution may be either a solution of hyposulphite of soda, or the ordinary cyanide of potassium solution. I prefer the latter, which always gives a sharper picture.

With this I conclude the articles on Pocket Camera, and I trust my instructions have been intelligible and useful to those amateurs who intended constructing a camera.

### DISTORTION.\*

It is understood, and taken for granted by many who are intimately connected with or practising the business, that a photograph is always correct. The impression has gone abroad that "the camera cannot lie," and all pictures recognized as photographs command implicit confidence; they are accepted as indisputable evidence in courts of law. It is said of a picture of an individual that it must look like him, for he sat for it; notwithstanding, his most intimate friends protest that it is not like him. Now, some of the causes that are productive of evil in this direction are generally over-looked. In the case of a portrait sitting, of course, the skill of the artist in posing, lighting, &c., has much to do with the truthfulness of the result; but there are other causes that should claim the attention of all photographers, especially in work that requires great precision, such as reproductions of maps, plans, geometrical drawings, or anything of that kind; and these are to be found in the contraction or shrinking of the negative film and the paper after printing and toning.

Dr. Vogel, writing in the June number of the *Philadelphia Photographer*, in reference to photographing the transit of Venus, speaks of the importance of obviating, if possible, the contraction of the film. To this end he has recently investigated the subject, and found that the contraction varies considerably with different samples of cotton. He says: "There are samples of cotton which contract very much, while others possess this quality in a lesser degree. I found that thick collodion contracts the most, while the limpid ones much less. "The contraction varied also with one and the same sample, according to its concentration. The same collodion which, with two per cent. of pyroxyline, showed a contraction, did not show any with one and a half per cent."

In reference to this same subject he writes also in the *Photographic World* for July, 1872, where he says:—"Rutherford works on albumenized plates, and states that with these no contraction takes place, and the author has tried these also. His experiments gave, however, a result which proved the opposite. The collodion on albumenized plates showed a greater contraction than on plain glass."

From this we should infer that a cotton made at rather a high temperature—the powdery, short-fibred cotton—would be best for work requiring great exactness. A collodion also that has become thoroughly ripe gives a less contractile film than a freshly made sample.

Ordinarily, however, the variation in the film presents no serious difficulty, except in astronomical photography, or

where a copy of a map or drawing is to be enlarged from a small negative. But we would suggest that, where nicety and precision are required, a plate somewhat larger than the impression to be made be used, so that the image may come on the centre of the plate where the film is of a uniform thickness. This will permit the film to shrink on all sides alike, and though there may be contraction there will be no distortion.

But the greatest variation is observable in the paper prints, where the shrinkage is sometimes so great as to utterly preclude the idea of correct measurement or proper proportion. We have seen a stereoscopic head—one inch in size, perhaps—where in one impression the head was nearly one-eighth of an inch smaller than the other. One had either expanded, or the other had contracted. One was fat, the other was lean. We have seen many portraits of friends that did not look right, and have no doubt that many of them were distorted from this very cause.

It is a matter to which photographers should give attention, and adopt such measures as will obviate the difficulty as far as possible.

### GLASS WOOL FOR FILTERING.

BY DR. J. SCHNAUSS.\*

OUR readers have no doubt heard of this new product of the glass industry. Till now it has been possible only to draw out glass in threads of appreciable thickness; but now, by altering the composition of the glass mass, it has been found possible to spin it as fine as silk, and afterwards beat it together like felt. From this substance all sorts of ladies' knickknacks are made, such as lace, feathers, and even hats; and chemists also employ it for useful purposes. To put into paper filters, for instance, especially when caustic and corrosive liquids are under manipulation, it is of great value, for it prevents these substances coming into contact with the paper and destroying them.

To the photographer, in this connection, this glass wool would also be valuable, for how frequently is a glass bath ruined from the fact that the filter paper which he has employed is not altogether chemically pure! Again, no inconsiderable quantity of silver solution is lost from being absorbed by filter paper after repeated operations.

A little glass wool pressed together, and stuffed into the upper part of a funnel, will suffice for the filtration of many silver baths; and when at last the wool becomes dirty from the accumulation of reduced silver and other impurities, then a little strong nitric acid is poured through it, and this at once dissolves and removes all solid matter. Washing out with distilled water will then render the filter as useful as ever.

For the filtrations of other liquids the glass wool is equally suitable, such as sulphuric acid, caustic potash, chromic acid; indeed, in these cases, it is without a rival. Its cost is rather heavy, being as much as six shillings an ounce; but it must be remembered that it is as light as feathers, and consequently a quarter of an ounce will last a very long time.

### PHOTOGRAPHY AT THE ANTIPODES.

BY J. H. B.

Adelaide, South Australia, May 18th.

ALTHOUGH, in this remote corner of the globe, we have but little opportunity of seeing the progress made in photography in Europe, beyond what we can gather from the columns of the PHOTOGRAPHIC NEWS and other publications, and we may probably be in the dark as to many matters connected with the art, I venture to offer a few Antipodean remarks, some of which may not be entirely

\* *Photographic Times*, U.S.

\* *Photographisches Archiv*.

without interest, perceiving that I write as an amateur who has practised photography for twenty-six years, commencing with the Daguerreotype process in 1848.

In this colony there are several professional photographers, and a fair sprinkling of amateurs; and it is a matter of surprise that so many of the former are able to gain a living in so small a community, as the prices they charge for portraits are by no means high. Occasionally I have seen what I have been able to designate pictures produced by some of them, but generally their productions are simple photographs—good, perhaps, in point of manipulation, but destitute of expression, feeling, or any artistic quality. A great distinction must, I think, be made between a photograph and a photographic picture: the former is the mere result of what may be termed a chemico-mechanical process, to a great extent left to its own action; while the latter is a genuine work of art, produced, it is true, by similar means, but in this instance guided by refined taste and artistic ability.

It is to be regretted that so few of the works of the artistic photographers of England and the Continent find their way to this colony, as a study of them might stimulate some of our operators in an endeavour to improve their style. I am aware that their chief object as professionals is to satisfy their customers at least cost to themselves, and I know also that artistic taste in South Australia is quite down to zero; but if our photographers had any taste or ambition about them, they would not be deterred from producing works of a higher class merely because it would not pay. These remarks have reference to portraiture; in other branches the professionals do little or nothing, and the views I have seen have generally been more deficient in artistic qualities than the portraits; all kinds of incongruities existing in them, such as figures standing in rows staring at the camera, streets taken exactly in the centre, the camera not four feet from the ground (giving them the appearance of being viewed by a person in a sitting position), blank white skies, insufficient exposure and development, and consequent want of detail, *eum multis aliis*.

It is difficult to imagine a country affording less good subjects for the landscape painter or photographer than this does. There is great sameness and insipidity about it. Nearly all the trees are of the same hue, and very similar in foliage and general appearance; and the almost entire absence of water, and the existence in all the settled parts of interminable straight lines of post and rail fences, are not conducive to pictorial effect. However, some pleasing bits may be obtained by a person possessing an artistic eye, who will exercise judgment in selecting proper positions for the camera, and times of the day when the effects of light and shade are good. I think I may safely say that twenty days in a year do not pass here without the sun showing himself. As a general rule the sky is without a cloud all day, and it would be inferred that the actinic power of the light would be very great; but, judging from the exposures given for certain dry plates in England, and that which I have found necessary here (the only means I have had of forming any opinion on the subject), it would appear to be comparatively feeble. It is possible, however, that I may be mistaken, and that the extreme dryness of the atmosphere renders the dry plate processes slower here than in England, where, even in the driest weather, the air is charged with moisture.

This climate is very favourable to printing operations, the extreme aridity causing the sensitized paper to become perfectly dry and crisp in less than fifteen minutes without artificial means, and the uninterrupted sunshine admitting of a large number of prints being secured in a short time. The great heat of summer (sometimes 156° in the sun, and 120° in the shade) produces difficulties both in the negative and printing processes, which, however, are not insurmountable.

## ALBUMEN AND CASEINE AS PRELIMINARY COATINGS.

BY CARL LUCKE.\*

In reference to M. de Constant's method of handling dry plates, I may, perhaps, be permitted to describe my plan of applying an albumen substratum. I am quite agreed with M. de Constant that the coating of a plate which happens to be wet on both sides, the plan usually adopted, is certain to bring about contamination of the silver bath. To render a glass suitable for the application of albumen, I proceed in the following manner.

I filter, in the first place, my dilute albumen solution, twice, and pour a quarter of it into a very clean glass vessel which is large enough to contain a two-inch or a two and a half inch flat camel's hair brush, such as is usually employed for dusting negatives. By means of this brush I coat, stroke upon stroke, the polished glass plate, and then pour from a lipped cup, which contains the remainder of the albumen (almost touching the plate) as much of the liquid as may be necessary to coat it. The superfluous liquid is allowed to run into the glass containing the brush, so that when the solution in the cup has been exhausted, it may be filtered twice and used again. The coated plate is allowed to drain thoroughly, and then placed to dry, standing upon a double sheet of filter paper.

By adopting this plan of coating the plates with albumen, there is no repelling action of the albumen, which runs over the surface of the plate as readily as collodion. The brush and glass vessel, after being employed, must be thoroughly cleansed, as one can very well understand.

A little while ago, I found that even with the most careful handling, my substratum of albumen produced little black spots upon the picture, just as if grains of sand had been strewn over the plate. For this reason I made some experiments with caseine, and my experience of employing this material is very favourable, for I have used it in my work with great success. The negatives obtained with a substratum of this material are exceedingly clear and fine, and the substance seemed rather to increase than diminish the sensitiveness of the collodion film.

My caseine solution I prepared in the manner following. Ten ounces of unboiled milk (measured by volume) are diluted with five ounces of distilled water, and coagulated with a few drops of acetic acid. The caseine is allowed to separate, washed twice with distilled water, and then the whole is collected upon a linen filter. The caseine remaining upon the filter is pressed thoroughly, and first washed with alcohol, and then with ether, to remove all traces of fatty matter. It is again filtered and pressed, and then dissolved in five ounces of ammonia and three ounces of distilled water, the liquid being filtered and put away for use.

Before coating the cleaned and well-polished glass plates, one part of this caseine solution is mixed with three or four parts of water, filtered twice, and then applied in exactly the same way as the albumen solution.

There is one peculiar advantage in this method of applying a preliminary coating to the plates. After the surface has been covered with caseine, and this has dried, the plates may be dusted without any risk, so that it is possible to coat plates long before they are wanted. Every care should be exercised to keep them as free as possible from dust; but this, unfortunately, will make its way into the best constructed plate box.

It is a question whether caseine could not be advantageously employed in the preparation of dry plates, and I hope that those gentlemen who suffer from the defects of an albumen substratum will give caseine a trial.

## TRUSTWORTHY FORMULÆ AND CAREFUL MANIPULATION.

WE print a letter on another page which may be said to be fairly representative of a large number of communications we receive. Our correspondent complains that the formulæ published by successful workers in the different branches of photography are often insufficiently precise to enable others to follow them, and secure similar success; and he refers to, and sympathises with, a complaint by a former correspondent, to the effect that he found it impossible to secure anything like the rapidity with various dry processes which their originators, and other workers, generally claimed for them. As we have said, the complaint is a very common one, and we naturally enquire, what is the legitimate remedy? There cannot be a doubt that precision in statement of formulæ is imperatively desirable, and that accuracy in the statement of the claims and qualities of any new process will save much disappointment. These facts scarcely need stating. But in looking for means of removing the cause of complaint to which we have referred, we must first ascertain whether the defects are really more due to the formulæ and those who propound them, or to those who apply the formulæ, and fail in working them out with perfect success. Possibly the causes of non-success may be, to some extent, divided; but it may be necessary to remind many photographers, in working out a process the details of which they have seen published, that the originator of a process is, as a rule, working for his own purposes of pleasure or business, and that when, with the liberality which has, fortunately, always characterized the best men in photography, he publishes the details for the benefit of the photographic community at large, he generally describes precisely his own usual mode of working. If, for instance, he says, "Add a few drops of silver solution to the developer," it is because he himself adds "a few drops" which are not counted, and may be eight, ten, or twelve. And so with many similar matters. The very fact that absolute precision is not employed in stating formulæ is fair indication, as a rule, that absolute precision in applying it is not necessary, but simply an intelligent apprehension of the general instructions. As a rule, the originator of a process, in describing it, is under the impression that he is addressing men more or less familiar with the class of processes of which he treats. He is too often, perhaps, under the impression that his readers possess experience somewhat similar to his. If he wrote

with the conviction that he was addressing many who are inexperienced, he would, probably, aim to be more precise. But in order to attain this precision it is probable he would in many cases have to repeat his operations for the express purpose of weighing, measuring, and otherwise noting accurately—a task involving an amount of time and care which, if necessary before describing a process, would often be sufficient to deter the experimentalist from publishing his process at all.

Let us glance at the case to which our correspondent especially refers, the beer and albumen process of Captain Abney, described in our last YEAR-BOOK. Some additional precision in statement might have been of value; but we cannot but think that little difficulty need be experienced in following the instructions given. The fact that, as our correspondent alleges, there is a vast difference in the manufacture of beer, is a sufficient reason why Captain Abney could not be precise in his description of the beer, as he would probably employ the ale regularly used in his household, the precise constitution of which he did not know, and the nearest approximation would consist in using the ordinary article known as pale ale, a potation most commonly used in the community. Possibly it would have been well to have been more specific, if possible, as to the quality of the malt liquor; but the probability is that most samples of ale would serve. As to the preliminary coating, there cannot be a doubt that a two-and-a-half per cent. solution of albumen means a solution of two ounces and a half of albumen to one hundred ounces of water. The statement that a plate is washed for a minute or two under the tap implies at once a slight latitude, and would suggest one minute, say, for a stereoscopic plate, and two minutes for a whole plate. Again, in directing a "final wash" of beer and albumen, after the statement that the first portion must remain half a minute on the plate, would at once suggest to us that the final wash simply consisted in flowing the preparation over the plate and off again. We have no doubt that Captain Abney will have pleasure in assisting our readers by the statement of any additional or more precise details which may be useful, and we should be well pleased if at all times experimentalists would use the utmost precision in stating formulæ and manipulations; but we feel it important to suggest that, as a rule, the details of a process being given to the public in the form the originator himself has worked them out, any insistence upon some different form, requiring re-examination of the operation, would often issue in non-publication altogether.

The failure of many photographers to obtain results equal to those obtained by the originator of a process is a troublesome problem with which we can scarcely deal fully now; but we may remark that, in relation to many of the dry processes for which rapidity has been claimed, that we have been present at various competitive trials, in which dry plates, worked as we have described at the time, have produced good results with exposures varying from that of an ordinary wet plate to three times as long; and that in the hands of a really careful and experienced worker like Mr. R. Manners Gordon, almost any dry process has produced good results, and, in its best conditions, rapid results; the gum-gallic process and the modified collodio-albumen process certainly not requiring more than three times the exposure of wet collodion with iron development.

## PHOTO OLEOGRAPHS.

OUR esteemed correspondent, Mons. Ernest Lacau, has more than once called attention to a mode of colouring portraits, which, under the name of "neo-oleo-painting," has recently obtained considerable vogue in Paris. It is not a little curious that in principle this method appears to be identical with one of the earliest plans of attempting to colour photographic portraits, a plan which has been

patented over and over again in this country. It was patented as early as the year 1852, and within fifteen months of the first patent two other specifications for precisely the same method were lodged at the Patent Office. In each instance the plan is described as consisting in making the photograph transparent by means of wax or varnish, and then, after being roughly coloured at the back with oil colours, mounted on paper or canvas, or any light ground which should give purity to the lights of the transparent coloured picture. In some cases this process was modified in after years by using two prints instead of one. A vigorous impression, being somewhat roughly tinted with vivid colours, was covered by another delicate impression, which had been made transparent, the latter being either placed in direct contact with the coloured print, or separated from it by a plate of glass, upon which the transparent print was often mounted with transparent varnish.

It is tolerably clear that by such a mode of colouring no examples of high art could be looked for, the artistic qualities of the finished work being chiefly bounded by those possessed by the original photograph. But it is also clear that pictures of excellence equal to that which is found in very much of the coloured photography which is issued may be so produced, and that they will at least possess all the fidelity of likeness and accuracy of drawing possessed by the photograph: qualities not unfrequently in some degree lost in the ordinary modes of colouring. In fact, photographs coloured in this way bear relation to an artist's work somewhat similar to that which belongs to the popular form of picture known as an oleograph, the results being, in point of fact, very similar. Photographic copies of good pictures printed on thin paper made transparent, coloured at the back, and then mounted on canvas so as to show its texture, as it is seen in an oil painting, might with advantage be produced, and while they might be made a popular form of art, could possess real educational value only second to that possessed by the original paintings themselves, they might at the same time form a valuable commercial branch of the photographer's business. Most of our readers are familiar with the details, both as given on former occasions in our pages, and as more recently described by Mons. Lacan. We may, however, for convenience of reference, repeat his account of an interview with M. Pettemans, as sent to our Philadelphia contemporary. After showing many fine examples, M. Pettemans coloured a picture in M. Lacan's presence.

"Here is exactly what he did. He took a positive print on ordinary sized albumen paper, and placed it on a retouching glass (sterolor), face downwards. It was the portrait of a man, album card size, rendered transparent similar to an image on wax-paper. He then opened a box in which were a dozen of those small metallic tubes containing the oil colours used by painters, a porcelain palette, a few fitch brushes, and two vials, one full of the liquid in which is first plunged the images to render them transparent, the other containing picture varnish. The operator placed on the palette a little each of brownish-red, blue, dark-brown, and prepared pink flesh colours; then on the end of his brush he took a little of the first tint, and put some of it on the back of the image in the places corresponding to the cheek bones, to the lips, and the shades in general. He operated in the same manner with the blue, which he applied under the eyes, around the outlines of the cheeks in the half tones; he laid on liberally the dark-brown in the place corresponding to the hair; finally, on the whole of the face and over all the tints already used he spread the flesh colour. He then removed the print from the glass, turned it over, and I saw a modelled painting with a proper gradation of colours, exactly similar to those that I had seen exposed in the gallery through which I had just passed. The operation had not lasted five minutes.

"It is certainly not the first time that prints have been coloured on the back so that, seen by transparency, they present the aspect of paintings, the photographs forming the drawing, and consequently the resemblance, if it is a portrait; but the former method required the hand of a more or less skilful artist. What is truly original in the process of which I speak is, that it is no longer necessary to know how to paint, or even to draw, to apply it; any ordinary workman, a child even, can perform it successfully. The tubes containing the colour are numbered, and it suffices to know that such a portion of the face corresponds to such a number, to make use of it properly; and this is learned in a lesson. It is the flesh colour, more or less light, yellow or red, and which is spread finally on all the other tints, which gives the particular character of the carnation, according to the person who has posed.

"I must add that when the colours are dry the print is laid upon canvas and pressed, so that the paper is moulded on the tissue, reproducing the hollows and reliefs so that the colour appears to be really on the canvas itself; varnishing ends the operation."

Another less familiar application of the idea of making one photograph transparent and placing it over another vigorous image, but in monochrome, has recently been revived. Some years ago the plan in question was patented in this country by Messrs. Lee and Thompson, and has on several occasions been brought forward, rapidly to disappear again from public attention. At the present moment some examples of this kind are exhibited in the photographic department of the International Exhibition at South Kensington, by Herr Stahala, as "chromo-photographs." The method of producing such prints was recently described at a photographic meeting at the Institute in New York, by Mr. Koans, of Karlstadt, N. J., who also used the term "chromo-photographs," in his case less inappropriate, because they are occasionally finished in colour. The details are thus given:—

"Two prints are made from the same negative, one on albumen paper, the other on plain; the last one is printed only far enough to show all details. By any varnish, thinned a good deal by spirits of turpentine, the albumen print is made transparent, and fastened to the inner side of an oval convex glass. This is done by a thick mastic varnish, or any colourless gum, as Canadian balsam, &c. Care has to be taken in this operation to get rid of all air-bubbles. Another oval convex glass is put at the back of this print, and the plain paper one is moved behind this glass till both prints appear like one; then a piece of white cardboard furnishes the back, and the whole is fastened together around the edges by sticking paper, and put in a suitable frame. For colouring these pictures, the prominent features— as eyes, lips, and the finer details in dress—are coloured on the back of the transparent albumen print, with thinner water colours; the rest is done on the plain print by dry colours being rubbed on pretty strong."

#### EDUCATING THE EYE.

The sight of one good picture is frequently more instructive than volumes of essays upon art principles, and no form of education is so valuable to the photographer as the frequent opportunity of seeing really good work. Perhaps nothing has so admirably illustrated this fact as the influence on the general quality of photography, especially in portraiture, exercised by the exhibitions of the Photographic Society during the last half-dozen years. Seven years ago such portraiture as adorned the walls of the gallery in Pall Mall last autumn was utterly unknown in this country. The resumption of the society's exhibitions in 1867, and the display of a series of the then scarcely known gems of Mons. Adam-Salomon, gave, we have no hesitation in saying, an impulse to photographic portraiture in this country such as it had not received before; and the quality of the work exhibited from year

to year has gone on improving, until now it seems a though it were scarcely possible to go beyond the best results recently exhibited. Photographic exhibitions are unquestionably the most efficient educators of the eye which can be devised, and if the Photographic Society had done nothing else for the art, it has laid all lovers of photography under a great obligation for the impulse to higher excellence which has been given by the society's exhibitions of the last few years. Such exhibitions are, however, only accessible in London, and at annual intervals, and they may, possibly, in the disorganized condition of the society, not be held again in a hurry, and our immediate object is to suggest to some of our readers other methods of obtaining valuable aid in their aim to advance in their art.

One of the most serious difficulties in the way of the young photographer in remote provincial districts is the want of standards of excellence before his eyes. With such standards, and the resolve to equal them, progress would be always certain, and often rapid. Without such standards it is possible to steadily work in the same groove for years, without alteration or improvement, the photographer acquiring, however, by long familiarity with his own work, an impression that it fulfils the ordinary conditions of good photography. Scarcely a week elapses that we do not receive examples of work upon which our opinion is asked, sometimes with hesitation and doubt, sometimes with a full conviction that it is of average excellence; the examples sent being, in a large number of instances, lamentably lacking in all the best qualities which a picture should possess. The senders, in a large number of cases, manifestly lack the educated eye which can distinguish a good picture from a bad one; and without this perceptive and appreciative power how is it possible that excellence can be attained? To educate the eye, then, is one of the first steps to excellence, and this education of the eye can only be obtained by familiarity with good work. Metropolitan photographers, and photographers in large towns, possess an immense advantage in the facilities they enjoy over their brethren in remote districts, and whose needs we have specially under attention at the present moment. There is, unfortunately, no organized method whereby the educational aids can be supplied. A correspondent of an American contemporary some time ago suggested the formation of an association amongst photographers, something like the Early English Text Society, and similar associations in this country, the aim of which should be to supply to all the members one or two superb photographs every year, in return for a subscription of from two to four guineas annual subscription. The idea is by no means an unattractive one, and for the subscription proposed, at least half-a-dozen very perfect examples might be supplied instead of one or two. Whether such a scheme would answer, if initiated, we cannot say. If such a project were successfully carried out, it would unquestionably have a valuable educational influence. Failing any project of this kind, however, we should urge upon young photographers, who have little opportunity of seeing the work of first-class men, the importance of losing no opportunity of purchasing fine examples for study and imitation: we mean imitation as to excellent qualities, not as to details. It would be a boon to such young students if some of the masters in the art would undertake to supply studies and examples at a reasonable rate. Failing this, the best plan is to select and purchase such examples of published portraiture as may possess qualities worthy of study and imitation in lighting, composition, arrangement, tone, &c. There are few photographers so remotely placed that no opportunity of this kind occurs to them; and having before us the evidence of its necessity in many cases, we urge upon all beginners and students in the art, to secure the primary condition of improvement and excellence, that education of the eye which comes from careful study of good examples.

### COLLODIO-CHLORIDE PICTURES.

THE main reason why the beautiful results of the collodio-chloride process are so seldom secured appears to be due, the *Photographisches Archiv* remarks, to the great instability of the chalk-paper usually employed as basis, as also to the circumstance that this particular paper is not adapted to photographic use.

A paper when it is newly received often yields good results, and after a while the pictures begin to show white spots over their surface, a defect which is always due to the paper, and need not be sought for in the collodio-chloride process itself.

To the above drawbacks may be added, in summer, the circumstance that the film easily rises from the paper, an inconvenience which cannot wholly be set aside by the addition of resin or oil of turpentine to the collodion, or by the use of cold baths.

Many skilful operators, who employ the collodion paper in large quantities, say that a first result will often succeed, while others produced subsequently are defective. The best substitute for chalk-faced paper would, no doubt, be one with a highly glazed surface of insoluble gelatine. Experiments conducted with transfer paper, made by Liesegang for the carbon process, give good results, collodion pictures produced on it being very beautiful, and their tone more pleasant than those printed upon chalk-paper. Moreover, when warm baths were used for toning, there was no trace of the film being dissolved away from its support. The gloss obtained with pictures of this kind was equal to that of albumenized prints.

The manufacture of a paper of this kind would, therefore, doubtless bring about an increased demand for collodio-chloride paper. Much trouble would be spared the photographer, and the public would obtain durable pictures with whites free from silver.

### PHOTOGRAPHIC IRRADIATION OR "BLURRING."

THE precise nature of the varied causes which produce a blurring of the outline, or spreading of light at times in the photographic image, has not yet been satisfactorily determined, and continues to be the subject of some discussion in *Nature*. When, a few years ago, the subject was discussed in photographic journals, it was dogmatically assumed by some to be solely due to reflection from the back of the plate; and as the use of a non-actinic pigment to the plate was found to be a cure in the majority of cases, this solution of the difficulty was generally accepted. The fact that a similar blurring or halation was sometimes present in Calotypes and Daguerreotypes where no reflection from the back of the plate could exist, was not worth discussing in the face of a cure based upon the reflection theory. The importance of freedom from such defects in photographic observations of phenomena like the Transit of Venus has again directed attention to the question amongst scientific experimentalists, and hence the discussion in the pages of the contemporary to which we have referred.

Mr. J. Aitken, to whose experiments we have before referred, writing to *Nature* again, and referring to the matter, says:—

"The conclusion to which these experiments pointed was, that there is a kind of photographic irradiation, caused either by the bright light producing an intense state of chemical activity, which has the power of extending itself in every direction; or, what seems more probable, the parts of the collodion on which the bright light is falling become luminous and reflect light to the surrounding parts of the sensitive film, and thus extend the chemical change on each side of the true optical boundary line. As the subject is at present under discussion, I send you the results of the following experiments, which seem to support the above conclusion. In a darkened room a vertical opening 18in. by 6in. was made in the shutter; over the opening was fixed a piece of

paper thick enough to stop most of the light, and only allow as much to pass as would give a decided, but not deep, photographic impression. Three long, narrow, parallel openings were cut in the paper; one opening was left clear to the sky, the next was covered with one thickness of tissue paper, and the third with two thicknesses of tissue paper. There was thus produced three parallel bars of different brightness on a uniform and darker ground. Sensitive wet plates were prepared in the usual way on glass and opaque black plates; across the front of the plates, and almost in contact with the collodion, was fixed a horizontal bar of thin blackened metal in such a position that it would cross the image of the luminous bars in the camera. The photographs, after exposure, were developed in the usual way, and it was found that the shadow cast by the horizontal opaque bar was not bounded by straight lines, but the ends of all the bright bars projected into the shadow, and the brighter the bar the farther it projected. I had no means of measuring accurately the bar and its shadow, but there seems but little doubt that the bright bars extended underneath the opaque bar, whilst the edge of the darker ground at the side of the bright bars gave the correct line of the shadow. Now this extension of the bright bars could not have been caused by the reflection from the back of the plate, as this result was always got, whether glass or opaque black plates were used. Nor could it have been caused by the oblique pencils referred to by Lord Lindsay and Mr. A. C. Ranyard, because, the opaque bar being close to the collodion, these pencils could not get underneath. The natural conclusion seems to be, that this extension of the bright bars must have been caused by some molecular reflection taking place in the collodion. This form of irradiation can easily be distinguished from the irradiation produced by reflection from the back of the plate, as the latter is simply a sort of haze surrounding the bright object, extending some distance from it, and gradually fading away, whilst the former extends a very short distance and has a well-marked outline, though not so sharp as those parts of the image where there is no irradiation. The irradiation produced by reflection from the back of the plate, and some forms of irradiation due to the imperfections of the lens, though fatal to artistic photography, yet do not interfere much with its scientific value, as they do not affect the accuracy of outline, though they do affect the clearness of the photograph. Molecular irradiation, on the other hand, whilst it scarcely affects artistic photography, is fatal to scientific accuracy. The manner of preventing this latter form of irradiation has been already pointed out, namely, by reducing the intensity of the light falling on the sensitive surface to only that necessary to produce a distinct impression. In artistic photography this is almost never possible, on account of the different amount of light on the different parts of the subject, while for scientific purposes this may almost always be done. The imperfections of the image due to the lens seem to be as various as the forms of lenses. One lens used in the experiments gave a curious double-hazy image of the bright object. When the image is near the centre of the 'field,' the double image fits over the true image, producing an effect somewhat similar to, and was at first mistaken for, the effect of reflection from the back of the plate. At first this double image was somewhat puzzling, as it always made its appearance, even when opaque plates were used. The two images were, however, afterwards separated by bringing the true image near the outside of the 'field,' when the true image and its double were photographed alongside of each other.

"The following simple experiment illustrates this molecular form of irradiation, and shows how much the definition of the image depends on the nature of the surface which receives it. Take a camera-obscure and throw the image on some translucent substance, such as opal glass; paint a small part of the glass with some opaque white substance; bring into the 'field' some brilliantly illuminated subject, such as branches of trees, against the sky; examine the image from the lens side of the glass, when it will be found that the image over the opal glass is hazy and indistinct, whilst the part of the image on the paint shines out brilliant and sharp."

Mr. A. Cowper Ranyard, writing in a subsequent number, says:—

"For the purpose of determining whether any sensible amount of the photographic irradiation surrounding the image of a bright object could be traced to an action taking place within the thickness of the collodion film, I some time ago tried an experiment in many respects similar to that detailed by Mr. Aitken in your last number. A piece of cardboard with four parallel narrow openings, each some 12in. long, was hung against the glass roof a photo-

graphic studio so as to be projected against the background of a bright sky. One of the slits or openings was covered with a piece of red glass, another was glazed with blue glass, the third was left entirely uncovered, and the fourth was covered by a piece of thin tracing paper. The slits in the cardboard screen were carefully focussed, and over-exposed photographs were taken with a camera in which no stops were used. Upon the collodion film, and immediately in contact with it, was laid a piece of platinum-foil quite thick enough to be perfectly opaque. The camera was so placed that the images of the slits fell partly upon the platinum-foil and partly upon the collodion film. I have now before me two of the plates, each taken with an exposure of five minutes. The first was coated in the ordinary manner with a single collodion film, but the other was coated three times successively with collodion, so that the film was rendered very thick; but the eating in or encroachment of the photographic images of the slits under the platinum-foil is hardly perceptible in either plate; indeed, I feel that I cannot say with certainty whether there is any encroachment of the image proper, though there are very marked brush-like extensions from the ends of the images, as well as a cloudy semi-circular field symmetrical with the end of each image, evidently arising from reflections from the back of the plate. At first sight the brush-like, semi-opaque extensions might be taken for the ordinary photographic irradiation eating under the platinum-foil; but on more closely examining the ends of the images, the hazy opacity is seen to extend farther in some directions than in others, and to be broken up in some cases into five or six little streams or brushes. The decrease in the opacity of the brushes is also less uniform than the decrease in the opacity of the ordinary irradiation border. The brushes extend to a distance of about 0.2in. under the edge of the platinum foil.

"I do not at present see my way to devise an experiment which would determine what is the cause of these little brushes, nor have I at present had an opportunity of repeating a similar experiment with the dry plate process; but the brushes have the appearance to me of having been produced by streams in the delicate film of liquid, which must extend under the platinum, streams which probably carry with them little masses of light-altered silver, that are soon deposited or strained out in the spongy tissue of the collodion.

"If the spreading action under the platinum foil were caused by light dispersed within the thickness of the collodion, one would expect such action to take place symmetrically around the place where the bright image is cut off instead of being broken up, as I have described, into bundles or brushes. On the other hand, slight differences in the texture of the collodion, or minute inequalities on the edge of the platinum foil, might cause the streams in the liquid film to move more easily at one point than at another.

"I should be glad to be informed what was the distance of the opaque bar from the collodion plate in Mr. Aitken's experiments, and whether there is not any photographic trace of defraction bands, owing to the bar not having been in focus; possibly the presence of these may account for the apparent difference in our results. It will be seen that the experiment which I have described points to the same conclusion as that formerly announced by Lord Lindsay and myself, viz., that the inner photographic diffraction edge is chiefly due to the imperfection of the instrument producing the image, chief among which is to be counted the aberration of oblique pencils."

Mr. W. J. Stillman, writing on the subject, says:—

"Mr. Aitken's observations on photographic irradiation in *Nature* are confirmed by many experiments I have made. I spent a long time in efforts to get rid of irradiation in bromide of silver films, one of the results of which I stated in a former note to *Nature*. There is the most striking difference in the behaviour of films containing iodide of silver only to those containing the bromide alone, the latter, especially when dry, giving much greater irradiation; and the difference is again complicated by the addition of certain substances (notably albumen) to the film in the course of preparation. As my experiments were mainly with dry plates, I will leave out of question the forms which the phenomenon may assume in wet-plate photography, and summarise the results of hundreds of experiments with dry plates iodized, bromo-iodized, and bromized.

"With a simply bromized film the amount of irradiation is extreme. The film is very translucent, and the irradiation is of two kinds, that caused by reflection from the back of the plate being by far the most extensive, but remediable by the usual expedient of coating the back of the plate with red or black colour, while the form noticed by Mr. Aitken is perhaps partially

inherent in bromized films, but to a much greater degree dependent on the nature of the pyroxyline. Two samples of pyroxyline made at different temperatures, and treated in precisely the same manner, differ so much, that while one will, with the coloured backing, give scarcely a perceptible degree of irradiation, the other will develop it to an extent which no backing, nor even tinting the film with the aniline reds, will obviate. The former is generally a compact, lustrous film, scarcely to be distinguished from the glass itself, while the other (both being used without preservative solution) will give a dull and dusty-looking surface, only capable of reflecting at very small angles. If with the latter a strip of blackened wood be laid on the film so as to cut across the lightest portions of the image thrown on it by the lens, the effect of the light will be found to spread behind the strip of wood sometimes to the extent of a centimetre; but I have never noticed the sharp limitation of this form of irradiation which Mr. Aitken observes, and which probably depends on the wet state of the film. It is clearly, as he supposes, an agitation which is set up in the film, and which depends for its propagation amongst the surrounding molecules upon a kind of chemical transparency in the film holding the bromide of silver. That this is to a great extent true is shown by two experiments. 1. A film which, in its simple state, gives considerable halation, will, when coated with albumen, especially if coagulated with nitrate of silver, give none at all, or very little, though the ocular transparency is rather increased than diminished by the albumen. 2. An emulsion prepared by exposing it to the action of nitrate of silver until it becomes structurally decomposed, and highly charged with bromide of silver, shows absolutely no irradiation under any circumstances, even if the glass be not backed, and no kind of preservative used. The film in this case resembles unbaked porcelain in its whiteness, entire want of lustre, and in opacity, and the molecules of bromide of silver are more than usually free from any restraining influence which a preservative might be expected—reasoning from the usual action of the albumen—to exert. In these two cases of extreme translucency and opacity of the film, there is almost an equal freedom from the phenomenon in question.

"In the old albumen process with translucent films the irradiation is imperceptible, and in the collodio-albumen, where the film of albumen is allowed to remain on the collodion, it is almost so; but in this case, as in all cases where the film is charged only with iodide of silver, there is another element which complicates the action. The bromide of silver is reduced *in situ* while the iodide requires a supply of silver from the developer from which to build up the image, in the one case the deposition being by reduction, in the other by accumulation. This alone would account for a wide difference in respect to irradiation, but will not account for all, as is proven by the diverse results obtained from different bromide films, due to the varying structure of the material which holds the bromide in place.

"What Mr. Aitken calls 'molecular irradiation' (and which is not by any means the harmless thing he considers it in regard to artistic photography any more than to scientific) is unquestionably the great enemy of all photographic precision. It seems, however, to be complicated with what I have been obliged to call structural irradiation, alluded to above, and depending, as I have said, on the mechanical, rather than the chemical condition of the pyroxyline of which the bulk of the film consists. The subject yet demands much investigation, of a purely empirical character, in order to determine the quality of vehicle for carrying the sensitive salts, neither chemical analysis nor chemical analogy affording any indication of the true cause of the difference between the two qualities of pyroxyline I have noted, nor do they, so far as I am aware, account for the difference between the action of collodion and albumen."

### THE NECESSITY OF PLEASING.

BY F. WALLER.\*

Much has been written and more said—especially of late—about the difficulties which beset a photographer's path. It is true they are manifold, and no one is more aware of them than the writer; but are not most of these obstacles to success, artistically and financially, of our own creation? Do we start with the fundamental idea of pleasing all who come? If we do not we are wrong, for this is an absolute necessity. It may seem difficult, but it is not impossible. It may be wearing upon your temper, or even seem to be

upon your pocket, at first; but the end will justify the means. Therein is the key to pecuniary success, which merely waits upon artistic merit.

Many complain that the public do not want, and will not take, good work. I never yet saw that class of people. Elevate the class of your work to the highest; your customers will progress with you. Please them, and in almost every case you will please yourself. Remember that when you present a picture to a patron it is the likeness he looks at; that is what he has come for. Yours is the task to see that in pleasing him you please yourself. All that is pleasing in a bad picture will be more so in a good.

When we reflect upon the vast quantity of wretched work which has been rammed down a forbearing public, "willy nilly," through the years that photography has become general, is it any wonder that sometimes our customers "kick in the traces"? The time has gone by for fighting your customers. Try the other road—please them. There is an old saying and a true one, "You catch more flies with molasses than vinegar." Re-sit them when they desire it, and if you have a good photograph they do not appreciate, try them with a better one. Do not (as the practice often is) exult over their ignorance, and when they sit again make them a poor one, because their taste and yours may differ.

One thing is certain: no matter how good a photograph may be, it can be improved upon. There is no goal in art; the highest on the ladder have still another round to climb. As a mere matter of policy, then, it appears that you must please your customers. The "art of pleasing," as the French term it, is open to all, and nowhere can it be better used than in photography.

### Correspondence.

#### SENSITIZED GELATINO PELLICLE.

SIR,—It is a curious fact in photography, that in all new processes, where there is the slightest chance of making a muddle, the process itself, and not the muddler, is sure to be at fault.

I am sorry to find from a letter written by "W. J. C. M." in your last week's issue, that I have been the cause of some uneasiness to him, for not only my pellicle, my instructions, the box the pellicle is packed in, but even the paper the poor little box is wrapped in, all come in for his displeasure. He goes on to say that from the positive way in which I speak in my paper of the certainty of the gelatine emulsion, he considered it his duty to try it. To whom, or to what this great duty is attributable he does not say, nor do I suppose it matters much; but I must say to him that when anyone undertakes to write publicly from a sense of duty of some kind, he ought, if he can, at least write accurately; not that I attribute a deliberate perversion of facts to "W. J. C. M."; all I say is that there should be more care used in "W. J. C. M.'s" letter, as it is likely to mislead.

"W. J. C. M." is particular to inform your readers that he followed out my instructions most carefully; but I will now undertake to show that he did nothing of the kind, and that the very departure from the instructions has caused the failure of which he complains. Will "W. J. C. M." or any one else point out in what part of my instructions he or they find that I advise drying by heat? If it cannot be found, what becomes of the truth of the assertion that the instructions have been carefully followed? I should advise anyone sufficiently interested in the matter to try the following, and report the result. Coat a plate, and let it partly dry, then finish drying the moistened part by heat; expose and develop as directed. The part dried spontaneously will adhere firmly to the glass, whilst that dried by heat will act exactly in the same way as described

\* *The Photographer's Friend.*

by "W. J. C. M.": it will burst up, and leave the plate thus proving that had the plates been thousands, instead of several, they would all have been failures.

I am afraid "W. J. C. M." is also affected with colour blindness, as he does not appear to distinguish the difference between yellow and white, for I can assure him not a single packet has been sent out with the scanty covering of white paper he so carefully describes: each and every packet that has been sent out has had a yellow covering. It is from not fully appreciating the excessive sensitiveness of the pellicle that so many fail to succeed. Some tell me they coated the plates by the light of a candle, others by a paraffin lamp, and then wonder how it is they get nothing but a thin image and fog. I only wonder they get an image of any kind, considering the pranks they play with the pellicle.

When I commenced, I did not intend writing so long a letter, and will now conclude by inviting any one really interested in the process to come and see it worked; and if "W. J. C. M." will favour me with a call, I have not the slightest doubt his next letter will be the very opposite of his last, and the numerous alterations and extra instructions which made him so heart-sick, he will find, are merely to simplify still more one of the most simple and rapid, as well as the cleanest, process out.—Yours truly,  
R. KENNETT.

#### NEW METHOD OF COMBINATION PRINTING.

SIR,—In reply to Mr. Bovey's very sensible remarks, I beg to say that he is quite right in his statement of my reasons for giving photographers a chance to find out my invention, as I should not like to sell it to any one if I did not think I was the inventor; and my reason for stating that I will give photographers my system of working if they point out the principle is, that no two photographers work exactly alike, therefore those who find it out must be the better off, on account of their having my system and their own, as I do not know what else I have to offer them for their ingenuity.

In regard to the system Mr. Bovey puts forward for obtaining combination prints, I have seen the same in the News some time back, of a gentleman stopping out the print on the sensitive paper, and then printing in the background. It was the interior of a room spoken of, so that I do not call that a new invention. In the time Mr. Bovey could print one in that way, I could print three or more, unless he is a very quick hand at stopping out. And in the plan Mr. Bovey puts forward, say a customer wanted a dozen cards, it would be rather awkward to have to sit down and stop out each print while doing your printing, with a few dozen pressure frames out, and he would find it rather difficult to stop out a young lady's flowing hair that intruded on the background, which my system can do, as my specimens will show. As I state, it is a quicker and better method than any other system, and I was fully aware of the system Mr. Bovey has put forward, having seen it in print.

I must keep my system till the time has expired, otherwise I shall not do justice to my photographic brethren. I own it is a challenge, but my reason for giving it is, that in future time another cannot say he had invented it before me.

I hope the hint taken by Mr. Bovey from my advertisement will open a new field of enterprise. I would be one to join in the fun.—Yours, &c.,  
W. TILLEY.

Stafford, July 20th.

#### ACCURACY IN FORMULA.

SIR,—In the notices to correspondents, on page 324 of the News, 3rd instant, T. W. Reynolds complains that he fails to obtain the rapidity "often described with a variety of dry processes." I can quite sympathize with him in this complaint, as the same experience is constantly my own lot.

I am far from insinuating that those gentlemen who kindly give their experiences to the world willingly withhold any essential information which might conduce to the successful working of their dry processes, but there is a want of definiteness, which no doubt constantly leads many workers into error. Take, for instance, Captain Abney's beer process. In the first place, the description of beer is not stated, and there is a vast difference in that manufacture. Secondly, he says he prefers to coat his plates with a 2½ per cent solution of albumen; and the first question that arises is, does he mean 2½ ounces of albumen to 100 of water, and if not, what is intended? Thirdly, after getting rid of the free silver by immersing the sensitized plate in distilled water, he says, "Then wash for a minute or two under the tap," but not one word is said as to the size of the plate so washed, and it stands to reason, that supposing Captain Abney uses 10 by 8 plates, and I use stereoscopic size, the amount of washing that my plate receives very greatly exceeds that which his plate receives; therefore it would be a great boon to amateurs, who have little time for experimenting, if some idea were given as to the size of plate requiring two minutes' washing; and the same remark applies to washing off the albumen coating. Again, a final wash of beer and pyro is given, no time being stated during which this solution is to remain on the plate. Such, Mr. Editor, are the principal defects in the description of Captain Abney's process, and I am sure he will only be too desirous of assisting those who have little leisure for entering into the minutiae above referred to. Now, sir, I am a very careful worker, but although I carry out Captain Abney's instructions as to bath, albumen, &c., and use distilled water for the first washing of the plates, I am perfectly unable to obtain the rapidity which that gentleman arrives at. I can vouch that the light I work by is quite of the right description, and that the materials I use are of the best. My lenses are also of the best kind, being Dallmeyer's rapid rectilinear; nevertheless, I require to give my dry plates, on an average, six times the exposure necessary for the wet process. How this is to be accounted for I cannot tell, but I am clearly not the only one who fails in the particular manner referred to by your correspondent, T. W. Reynolds. If yourself, or Captain Abney, will come to the rescue, I shall be extremely obliged.—Your obedient servant,  
DRY PROCESS.

## Proceedings of Societies.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE first out-door meeting of the season was held at Ravelston on Saturday, the 11th inst. The liberal proprietor, Mr. Murray Gartshore, kindly drove the party from Edinburgh to his estate, where they arrived about eleven o'clock. The day, unfortunately, was unfavourable for photographic work, in consequence of the prevalence of very high wind, although some very good negatives of the fountains and statuary were obtained, and Mr. Pringle secured several good groups of the members and their host. In consequence of the wind, some of the cameras remained unpacked, and their owners accompanied Mr. Gartshore on a tour of inspection through the grounds, with a view to another visit on a more favourable day. They then inspected the house, which is well worth a visit from all interested in literature and art, the collection of pictures being especially fine. The workshop and photographic laboratory occupied the rest of the afternoon, and the party were then entertained to dinner in right royal manner.

After dinner the members constituted themselves into an ordinary meeting, with Dr. John Nicol in the chair, and Mr. Barley was admitted an ordinary member.

Mr. PRINGLE said he wished to make a few observations in connection with what he had said at last meeting about Weston's rotary burnisher. When those observations were made he had not had much experience of the burnisher; and the little he had was not favourable, as it scratched the surface and produced irregular markings. Now, however, he was glad to say that after a few weeks' trial they were thoroughly satisfied with the machine,

and, in fact, did not think they could get on without it. He found that the scratch in the burnisher was easily removed by a boue, and the surface produced was such that in some cases prints too poor to pass muster looked first-rate after burnishing.

Mr. TURNBULL said he had no doubt that the burnisher gave a fine surface, but he maintained that his ordinary press, with the plate heated, gave one quite as good; and, in proof of his statement, showed some cartes finished by both machines, and it was impossible to tell which was which.

A hearty vote of thanks was then given to Mr. Murray Gartshore for his handsome entertainment, and the meeting was adjourned, the members reaching Edinburgh about eight o'clock, much pleased with the excursion, notwithstanding the unphotographic nature of the weather.

## Talk in the Studio.

**ART COPYRIGHT.**—Mr. Henry Blackburn, writing to the *Athenæum* upon certain difficulties in connection with art copyright, says:—"Within the last few weeks two rival processes have been perfected, by which almost any illustration can be reproduced in 'photo-relief' without engraving, and without the consent, even, of the nefarious publisher! Electros or clichés, almost identical with those cast from a wood block, are now produced by photography from any copy of a book or newspaper. A clear understanding, therefore, of the laws of copyright in these matters is urgently needed, both as regards England and foreign countries; and, I need hardly add, better laws. What is most needed at the moment is some system by which artists, and, more especially, photographers, can, without continual trouble and watchfulness on their part, protect themselves from having their works engraved without permission. With this view, it is proposed, by a company composed of artists and others, to form a central registry in London, where lists of all copyright photographs and drawings available for engraving will be kept, and a written authority given to the publisher on a payment of a small fee. This plan has been already adopted by the Berlin Photographic Company, and English artists and photographers will do well to take the hint. Publishers will certainly be the gainers, for the present want of system leads to trouble and confusion. Communications and suggestions on this subject will be gladly received by 'The Illustration Company,' 210, Strand, or by Henry Blackburn, Garrick Club.

**MICRO-PHOTOGRAPHY.**—At a recent meeting of the Royal Microscopical Society, Mr. Slack called attention to a slide exhibited under one of the society's instruments as being a remarkable specimen of Herr Müller's technical skill in mounting. The slide has photographed upon it, in an extremely beautiful and perfect manner, eighty spaces, with the names of diatoms below each, and a diatom of corresponding species was mounted in every space. Mr. Slack said he had received specimens of silica solution in the milky condition described by Mr. Reed at the last meeting, but was himself unable to detect any particles suspended in it, though some had been detected by Dr. Anthony. Mr. Charles Stewart described and figured on the board the peculiar position of the touch corpuscles in the skin of the hand, and he also exhibited and described a section of an ascidian, and explained the method of preparation.

**THE COMET.**—Mr. Norman Lockyer says:—"Ten minutes' exposure of a photographic plate gave no impression of the comet, while two minutes gave results for the faintest of seven stars in the Great Bear."

## To Correspondents.

**LEOPARD.**—Without knowing the history of the print, or the circumstances to which it has been subjected, which might have caused the spots, it is impossible to speak with certainty as to their origin. They do not seem to be due to imperfect fixation, but are more suggestive of the sensitive paper having come into contact with some foreign substance, which has slightly modified its character.

**F. T. D.**—Your second letter arrived too late for answer last week, but it did not affect our answer to both kind of spots. The carbolic acid is quite safe, and will not produce any bad result.

**X. X.**—Equal parts of ether and alcohol form the proper mixture wherewith to dilute collodion which has grown too thick by evaporation; but it is most important that the two spirits should be pure. Sulphuric ether is very apt to change. Merely standing for a time exposed to light, especially if the bottle be not full, will cause a change in the ether, which will become acid. This is probably the case with the ether you have used, which, by its acidity, has caused a decomposition in the collodion, by which iodine has been liberated, turning the collodion red. The loss of sensitiveness and effect generally are similar to that produced by age in the collodion. It would be wise to procure, if possible, the ether and alcohol used for dilution from the maker of the collodion; and, failing that, it is a good plan simply to dilute with new collodion, which is generally thin.

**H. C. COGSWELL.**—The use of sulphocyanides of potassium and ammonium as fixing agents in place of hyposulphite of soda received considerable attention some years ago, but these agents were finally abandoned, with considerable reluctance, because of certain serious drawbacks which made them unsafe as fixing agents. Experimental prints, produced with great care, might easily be obtained, possessing permanency; but prints fixed with ordinary care in a sulphocyanide solution would almost certainly darken afterwards when exposed to light. If you wish to make the trial, use a bath consisting of five ounces of sulphocyanide of ammonium in a pint of water, and after ten minutes' immersion remove the prints to another similar bath containing five ounces in a quart of water for a few minutes; then wash. If the first bath have three or four grains of chloride of gold added it will serve as toning and fixing bath in one.

**JOHN STONE.**—The sole use of ground glass with transparencies is to secure a soft white diffused light in examining them. If you attempt to examine a transparency without a piece of ground glass, or some equivalent means of diffusing and softening the light, you will lose much of the detail, and the lights, being quite transparent, will be disturbed by permitting objects to be seen through. In printing transparencies on dry plates, you of course bring the sensitive film into contact with the negative.

**M. S.**—We do not know, of course, what project you have of "checking" the unfair competition to which you refer, and could scarcely offer an opinion upon its legality if we did know. The assumption of a big name to which you refer is foolish enough, but we do not know of any plan of preventing such things. Our advice would be to leave the matter alone, and take no notice.

**D. R. F.**—Two causes may probably have been in operation in causing your films to dissolve when varnishing. It is possible your varnish may have been made with very strong alcohol or methylated spirit, and so possess considerable solvent power; and it is probable that your collodion has been made with pyroxiline which is soluble in strong alcohol; or, possibly, the pyroxiline has acquired that quality by some slight decomposition since the collodion was made. In any case, a coating of dilute albumen or gelatine applied to the negative film whilst wet will prevent any risk of the collodion dissolving whilst subsequently varnishing, or, if you apply your spirit varnish quite cold, and hold it before a brisk fire when the varnish is nearly dry; this will generally prevent the film dissolving, and also run no risk of chilling the varnish.

**TRY-AGAIN.**—As a rule, it is difficult to reduce an over-printed impression with any advantage. A solution of cyanide of potassium has sometimes been tried with advantage. After toning, fixing, and partially washing, the over-printed proof is placed in a solution of cyanide of potassium five grains, chloride of gold one grain, water ten ounces. When the excessive depth is removed, the prints are removed and the washing completed.

**NEO.**—It is quite optional as to whether you print any statement on a photograph or its mount, stating that it is registered. You may make the announcement, but it is not necessary to do so. Your copyright continues as long as you live, and for a term of years afterwards.

**C. C.**—If your sensitive plate and ground glass accurately coincide, and still the focus in the negative is behind the point for which you focussed, it is clear that the visual and chemical foci of the lens do not coincide. In that case, your only remedy is to make an allowance for the distance every time. 2. You should take care to test with a fine ground glass to make certain. If there be a serious difference between ground glass and dark slide it may be necessary to get a camera maker to rectify it; possibly you can make a slight adjustment yourself. 3. A stop should be a circle cut with moderate care.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PHOTOGRAPHS ON TOMBSTONES—PICTURES BY THE WAY— PHOTOGRAPHY UNDER DIFFICULTIES.

*Photographs on Tombstones.*—In November of last year we made allusion in this column to the custom gaining ground on the Continent of placing photographic portraits of deceased persons upon their gravestones, and we pointed out that if the matter became general, then this would be, before all others, a direction in which enamel photographs might be employed with great advantage. Recently we have been informed that in England—at Shrewsbury, to wit—the practice of putting up *in memoriam* photographs in the churchyard is also rife, and we may anticipate, therefore, the possibility of the custom becoming more widespread. At the Père-la-Chaise and Montmartre cemeteries, in Paris, the neat iron crosses which there take the place of stone ornaments are sometimes to be found fitted with photographic pictures; but as these are for the most part paper productions framed with glass, they are ill-fitted to withstand the effects of the weather. Moreover, if any accident happens to the glass, or the framing is carelessly done, wind and water soon make their way to the perishable portrait, and destroy it. The only satisfactory solution to the problem will, therefore, be the employment of enamel pictures, and photographers who occupy themselves with the preparation of these beautiful productions will doubtless soon have increasing demands for such pictures made upon them. The placing of portraits of deceased persons in cemeteries and churchyards is by no means of recent date, for we could point out many a retired spot among the Alpine villages where the habit has obtained for many generations past; at any rate, the productions of the native artist upon the upright wooden boards scattered about the "Godsacre," reminding one of the ill-executed sign-boards one sees at English roadside inns. Indeed, the village painters, so far as our experience goes, never got beyond the depiction of something horrible, the weird faces around looking more pale and ghastly the older and more weather-beaten they became, the effect upon the visitor being such, in some of the quiet churchyards, as to cause him to beat a hasty retreat from the enclosure. It will be an important improvement, therefore, when little black-and-white photographs, no matter how badly executed, come to take the place of those horrible daubs and uncanny representations.

*Pictures by the Way.*—There is one point which amateur photographers will do well to bear in mind when strolling through a country with the camera. It is this. No matter what landscape or view is to be taken, it is always well to secure in it a habitation or building of some kind that shall be characteristic of the district. Indeed, it will be found that pictures taken of villages, cottages, huts, &c., will always pay better than mere views and landscapes, waterfalls, lakes, &c. There are exceptions, of course, but there is a strange similarity between the natural beauties of one country and another. If you take a picture of some gigantic Swiss waterfall that comes tumbling down two or three hundred feet, it is necessary to retire to some distance to get the whole of the effect upon your plate, and the chances are that you do not secure so good and grand an effect as that of a much more modest cascade, taken at close quarters. Proportion has a great deal to do with the matter. Hills a couple of thousand feet high appear to the eye from certain points of view quite as lofty as those of seven or eight in other places. Thus Cader Idris, or Snowden, from the fact that they are the monarchs of their district, and are surrounded by other mountains and hills in proportion, look sometimes quite as important, in their way, as the Rigi or Pilatus on the lake of Lucerne, because there are other peaks near

at hand which are higher again than these. Characteristic scenes from nature—such as the crystalline glaciers and snow cornices of Switzerland, the soft lake scenery of Italy, the wild crags of the Tyrol, and the gigantic mountain walls that border the Norwegian Fjords—are obviously all worthy of depiction, but, nevertheless, representations of them are much enhanced by the presence of a rustic hut or dwelling in the sketch. Amateurs will find that the more pleasing reminiscences are always those that show something of the life and customs of a country, and do not merely portray its natural beauties. A quaint chalet, an ancient German burg, a village street, or an old-fashioned bridge afford pictures which will be more highly prized hereafter than any secured of mere mountains or valleys. One word more on the question of snow scenery: we have ascended Ben Nevis in June, and seen snow cornices as soft and beautiful as those of Switzerland, and we think that a photographer making the ascent early in that month, or in May, might be able to pick out many little bits which would have all the characteristics of Alpine photographs.

*Photography under Difficulties.*—If some ingenious inventor would improve upon the *Pistolgraph*, and give us a *Riflegraph*, or something of the kind, there would be a use for it. The other day a photograph of a military balloon was required to be taken, to the car of which a steering apparatus had been attached, which was to do wonders in making the bulky machine sail in the teeth of the wind. A picture was desired showing the balloon floating in the air, and under the influence of this apparatus, when at some distance from the earth. Under these circumstances, the best instrument for taking the picture would have been one that could have been levelled at the balloon when flying, the photographer taking aim (by looking through a cylinder, or something of the kind), pulling a trigger to expose instantaneously as soon as he could cover the object. As it was, unfortunately, it was so difficult to judge beforehand of the course of the balloon, and the influence of the steering invention (which turned out to be *nil*), that only an indifferent result could be secured with the ordinary camera and apparatus.

### PHOTOGRAPHIC IRRADIATION OR "BLURRING."

THE following further correspondence on this subject appears in *Nature* :—

"In answer to Mr. Ranyard (*Nature*, vol. x. page 206), I have to state that the opaque bar in my experiments was placed as close to the collodion as possible without touching it, not farther than .01 inch from it, and that there were no photographic traces of diffraction bands.

"Allow me now to suggest a possible explanation of the different results given by Mr. Ranyard's and my own experiments. One important difference in the arrangement of the two experiments was, that in the one case the opaque bar was in contact with the collodion, and in the other case it was placed at a very short distance from it. In the experiments with the bar in contact with the collodion, the nitrate of silver solution on the surface of the plate would not form a true plane, but would be curved upwards at the edge of the bar; and further, this curve would not be regular, but would have irregularities corresponding to every irregularity in the edge of the bar. This irregular curved fluid surface would cause irregular refraction of the light falling at the edge of the bar, and would give rise to bright and dark parts on the sensitive surface; the bright parts would be extended by molecular irradiation underneath the opaque bar, and would give rise to the irregular brushlike projections mentioned by Mr. Ranyard, instead of the uniform extension obtained when the bar is kept a short distance from the collodion. It is also possible that the irregular curved fluid surface may at certain points, where the bar was not in actual contact with the collodion, have bent the rays of light underneath the bar, and given rise to the irregular extension of the image.

JOHN ATKEN.

"Darroch, Falkirk, July 18."

"I must confess myself at issue with Mr. Stillman as to the result of his experiment with the strip of blackened wood laid upon the collodion film. I have tried a similar experiment, and find the images of bright objects sharply cut off. Even with a film of four thicknesses of collodion and an exposure of ten minutes, I cannot detect the smallest encroachment. The minute brushes mentioned by me in my last week's letter only occasionally occur, and appear to be due to a circulation in the liquid film beneath the opaque object, probably caused by some chemical impurity, for I notice that the brushes only occur when the film beneath the opaque object is soiled.

"It cannot be argued that because there is a difference in the amount of irradiation in two pictures taken by different processes (instruments, exposures, and other conditions being similar), that therefore the spreading action must take place within the film, for the plates prepared by the two processes may not be equally sensitive, and the pictures may really correspond to what, with the same process, would be different amounts of exposure. Or, again, the relative rates at which faint and intense light imprint themselves in the two processes may differ. Want of sensitiveness to the action of faint light is, I imagine, the reason why irradiation is apparently decreased by the use of the red collodion.

"A. COWPER RANYARD."

#### ART PRINCIPLES FOR PHOTOGRAPHERS.\*

68. It is gratifying that the days of white pictures have passed, and it has been demonstrated that extensive shades are admissible in a portrait, as well as in a landscape where rocks and hills cast their grim shadows and give grandeur to the scene; that a face may receive the same treatment at the hands of an artist that nature accords to her works everywhere, and be more truthful, more pleasing, more life-like. The shadows and middle tints give support and brilliancy to the lights; there is no glare; the eye does not tire, but wanders from point to point, continually attracted by the sense of completeness and repose that characterizes the whole. An important consideration in a bust portrait is to give it a well shaded background, the deepest parts against the lights in the model; this is indispensable to the brilliancy and beauty of the face.

69. In the more elaborate compositions of figures and accessories, shadows may be made effective by a judicious arrangement of the several parts, especially the draperies, the whole being based on some part in which the depth of shadow culminates, and from which the eye is led to the principal subject of the composition. In reference to this mass of shadow, whether in a bust or full-length portrait, it need hardly be observed that, even where most vigorous, it should not be a mere blot which obliterates wherever it is extended. The occasions are very few where either the form or the proper colour of objects can be thus totally lost, because objects in the strongest shade are only deprived of direct light; they are more or less illuminated by the surrounding atmosphere, and the reflected lights from other objects.

70. This is a point that requires great care on the part of the photographer: to so arrange his light that the form and detail in the deepest shadows will be given. In many of the so-called Rembrandt or shadow pictures this is a grievous defect, and mars the beauty of many an otherwise beautiful production.

71. The artist with brush and colour may give the form in shadow at will, and study the effect of every touch he makes; but the artist photographic has not the same control over his work after the impression is once made, except by retouching the negative; and the basest use of that indispensable adjunct of the art is in supplying what is actually lost or wanting. In a perfect negative impression there should be nothing lost—no blanks of either light or shadow. As all means are legitimate in producing a work of art, so long as the method is not apparent in the result, the photographer should not

hesitate to avail himself of any device that will assist him in representing the truth of nature.

72. When in producing the shadow effects the hair is dark and gives too heavy a mass of shadow, it may be lighted with a slight touch of powder so as to give all the detail, and yet not appear in the finished picture that any artifice whatever resorted to. This is much better than using reflected light in the shadow, so long as the face does not need it. One of the worst effects that can be produced is the wasting of a natural shadow by throwing in a false light for the purpose of illuminating some other part. It is much better to employ some of the more happy artifices, such as a little paint or powder, a little different arrangement of the folds of a drapery, which may be made to break up too dense a mass of shade, or the contracting or extending of accessories so that reflexes may be obtained wherever they will produce the best effect.

73. In no direction, probably, have photographers erred so much as in the use of accessories; and yet there is scarcely one pictorial subject that does not require the expression and character obtained by the introduction of some accessory.

74. Nothing has so bad an effect as a picture crowded with accessories that have no connection with the principal subject. Many good artists run to excess in this direction, and all rules of art and good taste have been so outraged by the great mass that have used accessories indiscriminately, without regard to fitness or effect, that the demand for pictures of this style has almost entirely ceased, and the bust picture, with but little more than the head and shoulders, has become most in vogue.

75. It is not to be understood, however, that accessories consist only in the objects that may be placed in the picture independent of the subject, such as chairs, tables, columns, &c.; but the drapery that may compose the costume is an important accessory, requiring taste and skill in its arrangement.

76. It is universally allowed that Raffaele excelled all other painters in a graceful arrangement of drapery, and a natural disposition of the folds. By studying the principles of the ancients he learned to consider the figure as the principal part, and that drapery should be regarded as an accessory; that it is intended to cover, and not to conceal; that it is employed not from caprice, but from necessity; consequently, the dress should not be so narrow as to constrain the members, nor so ample as to conceal them, but suitably adapted to the size and attitude of the figures represented.

77. The photographic artist has his drapery under his control quite as much as the painter, and there is nothing in connection with composition that requires more careful study and a closer observance of nature than the disposition of draperies. Even in the simple bust picture, where there is so little to display, its effect is wonderful in giving a proper balance to the lines, and contributing to the unity of the whole. But how much more important is it in a full length figure, where its flowing lines and graceful folds may be made to not only give support and symmetry to the subject, but breadth and force to the whole, by a proper distribution of light and shade.

78. Variety in the use of accessories is a necessity that stimulates study and invention. Nature never repeats herself even in two sides of a leaf; such precision belongs only to machine work; and in studying nature we learn that variety is no less necessary to a pleasing composition than unity. It is the want of this that has compelled so limited a use of accessories at the present time. The incongruity of photographing lawyers, statesmen, artists, farmers, preachers, ladies, and babies, all with the same surroundings, became too monotonous to be tolerated, and those who could not remedy the evil and retain the style, have done well to substitute a style that was quite sure to give the variety that nature furnishes in the ever varying phases of human forms and features.

79. A judicious use of accessories requires that they should correspond with the character of the subject. If it is light and gay, a much greater variety of objects may be admitted than if it is grave and majestic. By multiplying objects, a greater variety is obtained in line and light and shade, which contributes to gaiety. A variety of objects is inconsistent with the simplicity so essential to the grand style. The best works of art—those that are the most pleasing, the most enduring, and produce the most forcible impression—are always characterized by simplicity. In pictures of this character, variety must be considered with reference to that undivided attention which a great subject demands.

80. In the use of accessories proportion is an important consideration. It is requisite in everything intended to please the eye. In works of art it refers first to size; next to the degree of light and shade; and again, to the force of expression required in the character of the scene represented. Any work is in good proportion if its details are neither too large nor too small when viewed in relation to the whole or to each other. For example: if a man be surrounded with furniture the proper size for a child, he would be made to look like a giant; while on the other hand, immense secretaires and mammoth chairs dwarf the subject, giving it an air of weakness and inferiority.

81. Harmony is an important element in a composition. There must be harmony of line, harmony of grouping, harmony of light and shade, harmony of expression. Each part must be so adapted as to correspond with the rest. The attitude must be in keeping with the expression; and the accessories must be true, both to the character and the age represented. A harmonious whole is always more or less pleasing in itself, independent of subject or style.

82. Lastly, breadth is essential to harmony. According to Allston, "by breadth is meant such a massing of the quantities, whether by colour, light, or shadow, as shall enable the eye to pass without obstruction, and by easy transitions, from one part to another, so that it shall appear to take in the whole at a glance." To this unity is essential. When the objects introduced in a composition are multiplied, scattered, and divided, the eye, in searching for the principal object of interest, becomes wearied and perplexed, and the picture is then said to want repose. Unity, however, is distinct from harmony, and requires one point of view, one focus of light, one prominent character or group, one leading idea. There may be unity of parts when harmony in the whole is entirely wanting. Accessories, then, should only be used as such, and correspond with the subject, that the eye will be led involuntarily to the principal figure, while all else remains subordinate and dependent.

#### ON THE ACTION OF PIGMENTS UPON SENSITIVE SILVER SALTS.

BY PROF. H. VOGEL.\*

IN April last we referred to some experiments made by Lea with bromide of silver. Lea impregnated some bromide of silver films with colouring matter, and exposed them to light under coloured glasses. He thought to obtain in this way results similar to those I received with the solar spectrum. That this was impossible I have already said in the April number of this journal. Pigments and the colours of the spectrum are widely different things, and only rarely is the action the same. In the spectrum, red and yellow act upon a collodion film like black, and blue like white. This agrees in many instances, but by no means for all. One of the best known blues—the indigo of the Prussian infantry—is not rendered white, but is represented as dark in a photograph as in nature; while one of the best known reds—madder—does not become black, but almost white, in a picture. Aniline red is

rendered like white paper; and Naples yellow not black, but grey, when depicted by means of the camera. A mere glance at the colour table in my manual, which shows the results colours give in photography, suffices to prove that the action of pigments cannot be summed up by the rule that blue always reproduces a light tint, and red and yellow dark ones. And if this rule does not hold good with coloured bodies, it is much less correct in the case of transparent tints.

All pigments are impure; that is, they consist of several colours of which our eye perceives but one. It is only the spectroscope that can give a decision upon the mixture of colours. If an indigo or Prussian blue surface is looked at through a spectroscope, the colours are seen separately, and the eye is able to appreciate them. It is then seen that in indigo or Prussian blue there is an appreciable quantity of red, and in madder a great deal of blue and violet. If Lea is right in saying that a mixed colour has the action of the dominating colour that we see with our eyes, then Prussian blue would give a white result, as is not the case; and madder, Naples yellow, ochre, &c., would yield dark impressions, as we know they do not.

Those who experiment with impure colours are in the same position as a chemist or photographer who employs impure chemicals.

What would Mr. Lea say if I were to test his dry bromide plates, and use for the purpose impure collodion, as also impure bromide salts, acids, and silver salts, and badly cleaned plates? I believe he would scarcely think it worth his while to criticise bad results obtained under these circumstances. Is it not pretty well the same, then, when an experimenter works with impure colours, and hopes to secure the same results as those given by spectrum colours? And when one comes to hear how Mr. Lea has conducted his experiment, the matter becomes stronger still.

I observed that bromide of silver mixed with aniline red was acted upon vigorously by the yellow rays of the spectrum—that is, those rays were energetically absorbed by aniline red. If, therefore, a red tinted bromide of silver film is covered with a glass coated with aniline red varnish, it is clear that the aniline red varnish will absorb the yellow rays. The penetrating light does not, then, any longer contain the yellow rays, which, according to my observation, act upon bromide of silver. Obviously, therefore, this action cannot take place. If it does, it is due to blue rays that have penetrated.

Now, says Mr. Lea, exception cannot be taken to these experiments, because in many cases the same pigment was used for colouring the bromide film as was employed for tinting the glass over it. This statement is sufficient to condemn his experiments, because obviously he has cut off those coloured rays which, according to my experiments, are just those that act upon the bromide of silver.

The conclusion is, that phenomena such as I have observed can only be obtained with pure spectrum colours, and not with impure pigments. Mr. Lea avows one thing more. He remarks that solacine, according to his experiments, greatly augments the sensitiveness of bromide of silver for the yellow and red rays, although it is absolutely colourless, and therefore absorbs no colour at all.

Mr. Lea appears to have overlooked the fact that there are colourless bodies which show vigorous lines of absorption in the spectroscope, such as atmospheric air, vapour, the salts Didym and Erbium. If he is not aware of such absorption power existing in solacine, it does not follow that it is not there.

Besides, my observation is not the only one of the kind. Nitrate of silver is a colourless body; but, according to my experiments, it has especial sensitiveness for violet and blue rays (*Mittheilungen*, 1874, p. 233); and colourless morphia increases, in my experience, the sensitiveness for green, yellow, and red—a result which, to those who know of the absorption of colour by colourless bodies, is nothing extraordinary.

\* *Photographische Mittheilungen*.

The spectrum colours differ materially from ordinary pigments, not only in the matter of purity, but as regards brightness, which has also much influence upon the result.

The yellow of the spectrum is, according to Fraunhofer's and Vierodt's experiments, a hundred times brighter than the indigo of the spectrum that acts most energetically, speaking photographically. Such intense brightness is possessed by no yellow pigment.

Compare, for instance, the chrome yellow in my colour table with the ultramarine, and one would say that the yellow is at least double as bright as the blue. If, then, I observe an action with a spectrum yellow fifty times as bright, equal to that of the spectrum blue, it follows, as a matter of course, that the matt chrome yellow, compared to the blue, cannot produce a similar action. We must, therefore, enhance the sensitiveness of bromide of silver for yellow fifty times before we get an action from chrome yellow. My experiments lead me to hope that this goal may be reached.

The above may be taken as a criticism on the experiments with coloured glass undertaken by Lea, Spiller, &c.

More recently Dr. Monckhoven has published a series of experiments with the spectrum itself, and this gentleman has been unable to secure the results attained by me. He remarks that if my experiments prove right, they will influence the focus points of photographic lenses, and he therefore repeated my experiments with the best constructed apparatus. He employed a spectroscop of flour flint prisms and condenser, &c., with which he obtained a spectrum of forty centimetres.

I envy my worthy colleague such an apparatus, which, unfortunately, was not at my disposal, for I could only obtain for my experiments one throwing a spectrum of six centimetres. I only wish the precision adopted by my colleague in regard to his apparatus had been observed also in his communication. In reference to this I must remark that Dr. Monckhoven quoted my results with much lack of precision.

I was not a little surprised to read in the *British Journal* of 19th June, page 292, that, according to Dr. Vogel, a bromide of silver plate is only sensitive to rays more refrangible than green. That is rather wide of my remark (*Mittheilungen*, 1874, page 234), which is expressly to the effect that dry bromide of silver is sensitive to the orange rays.

It is, further, an incorrect repetition of my statement when Dr. Monckhoven says that I affirm "that by adding to the bromide of silver any colour which absorbs a certain part of the spectrum, the maximum of sensitiveness in the bromide will be found in this portion." Of this there is nothing in my communication; I only said that coralline plates showed themselves almost as sensitive to yellow rays as to indigo. Only in the case of chloride of silver does the maximum effect reach to the yellow when naphthaline red is used. I am, moreover, much surprised that Dr. Monckhoven reports that I employed only one prism of flint glass, when I stated that I used a spectroscop *à vision directe*. As erroneous is the description of his own experiments.

He exposed a *wet* collodion plate to the spectrum, and found it sensitive, at the most, as far as line 1,450 of Kirchhoff; or, in other words, to green. It does not transpire, however, whether the *wet* plate contained bromide of silver or only iodide of silver. I took it to be of the former character. Then he says further on: "Bromide of silver in wet plates is not more sensitive to green than iodide of silver." He then says that he has tried fuchsine, coralline, &c., and repeated his experiments in every form, and yet obtained no traces of sensitiveness to yellow and red. Finally he adds that, if he is rightly informed, similar (negative) results have been obtained in Bunsen's laboratory at Heidelberg, that an illustrious French physicist (name?) has also been unable to secure results, and that

from the Ecole Normale, the Conservatoire des Arts et Metiers in Paris, Mr. Norman Lockyer, Mr. Spiller, Col. Stuart Wortley, and Mr. Lea, the same negative results are reported. There is, therefore, a perfect array of opponents in the field, whose names alone suffice, according to the *British Journal*, to give my results the *coup de grace*, and banish them altogether.

Of Lea and Spiller's assertions I have already spoken. Experiments made without the spectrum can never be taken to contradict those undertaken with it, any more than experiments without collodion can be employed in combating collodion investigations.

As to the other gentlemen mentioned by Dr. Monckhoven, I have read nothing of their statements, and cannot, therefore, say anything. Fortunately, however, Dr. Monckhoven himself furnishes me with a means to contradict all the assertions. He anticipates that my results with red light may be produced by the action of diffused light, which comes through the prism, for he says that he is quite convinced that Dr. Vogel's plates show neither line D, nor line C, nor lines B and A of the solar spectrum. I have however plainly photographed lines E, D, C, B, and *a*.

"The publication of a photographic spectrum in one of the journals is the practical plan for Dr. Vogel to prove that he has discovered a new process for the photographing of the yellow and red portions of the spectrum, and would be a direct proof that he has really obtained the results in question," says Dr. Monckhoven. I am very grateful to my colleague for this hint, and shall take the opportunity of making public several photographs of the spectrum which have been submitted to the Academy of Sciences.

In the meantime I may say a word upon Dr. Monckhoven's non-success. He employed a slit of only  $\frac{1}{50}$  m.m., while I used one of a quarter of a millimetre. For this reason his spectroscop admitted but seven and a-half times less light than mine. His spectrum stretched to forty centimetres, seven times longer than mine, and, therefore, the brightness of his picture was 7 by  $7\frac{1}{2}$ , or fifty times weaker than mine. I required exposures from three to fifteen minutes. If Dr. Monckhoven desires to obtain the same result with his weak spectrum, one hundred and fifty minutes' exposure would be necessary. Instead of this he gave two minutes. That explains a good deal. The non-success with coloured plates has still another cause—he has most likely coloured them too highly. At the first glance, one might think that much colour would be beneficial. My first experiments proved to me the contrary with naphthaline red and aldehyd green, and the explanation of this is easy.

Every particle of bromide of silver is surrounded by an envelope of coloured collodion. If the colouring be too dense, the light is too much weakened by absorption before it gets to the bromide of silver, and is not then in a position to act vigorously enough. I prepared four plates, Nos. 1, 2, 3, and 4, of which each was half as strongly tinted as the previous one; the one least tinted showed the highest sensitiveness for yellow rays, the darkest showed no action at all. More anon.

#### GLUE AND ITS USES.

WE condense from an article in the *Boston Cabinet Maker*, originally derived from *Tomlinson's Dictionary*, some hints upon glue and its various uses which may prove useful to our readers.

The better sorts of glue are transparent, especially the thin cakes of the Salisbury glue, which are of a clear amber colour. The best glue swells without melting when immersed in cold water, and renews its former size on drying. The method of softening it for use is to break it into small pieces, soak twenty-four hours in cold water, and then melt

slowly over a fire with frequent stirring. When prepared in this way it cools down into a stiff jelly, which requires only a little warming to fit it for use. Glue must not be used in a freezing temperature.

A strong compound of glue is made by infusing common glue in small pieces with isinglass in spirits of wine, just sufficient to cover the mixture. Heat is then cautiously applied, and when melted, powdered chalk is added, making the whole of an opaque white. A strong glue, which will resist water, is also obtained by adding half a pound of common isinglass to two quarts of skimmed milk, and evaporating the mixture to a proper consistency. If gelatine, which has been swelled in cold water, be immersed in linseed-oil and heated, it dissolves and forms a glue of remarkable tenacity, which, when once dry, perfectly resists damp. Ordinary glue may thus be dissolved, and a small quantity of red lead, in powder, added.

It appears from the observations of M. Schattenmann, a glue-maker, that fresh glue dries much more readily than glue that has been once or twice melted; and that dry glue steeped in cold water absorbs different quantities of water according to the quality of the glue; and the proportion of water so absorbed may be used as test of the quality of the glue.

It appears that fresh glue contains water of composition, or water more intimately united with the glue than water mixed with it in the process of melting, which admits of being readily disengaged by evaporation. The combined water of dry glue disappears in the course of successive meltings and solidifications to which glue is subjected. Glue in thin plates is usually of better quality than thick ones, even when made with the same kind of gelatine, because the thin plates admit of a more complete drying than the thick. In applying M. Schattenmann's test, dry glue is immersed for twenty-four hours in water at the temperature of about 60° Fahr. A jelly will thus be formed, the qualities of which will fairly represent those of the glue. For example: the finest ordinary glue, or that made from white bones, absorbs twelve times its weight of water in twenty-four hours, so that a plate weighing three grammes produces thirty-nine of fine elastic jelly. Glue from dark bones absorbs nine times its weight of water, and produces not quite so fine a jelly. The ordinary glue of Alsace or of Germany, made from animal refuse, absorbs five times its weight of water producing a soft brown jelly, without elasticity and consistence, and falling to pieces when handled. The common glue of Boulogne absorbs three and a half times its weight of water.

Well-dried glue is much less hygrometric than badly made glues, or those made of inferior materials. The latter are liable to putrefaction. The water of composition seems to be injurious to the strength of glue, which increases in proportion to its dryness.

"Glue or gelatine has lately been applied, with great success, to the formation of moulds for castings. The difficulties attending the use of sands, clay, plaster of Paris, wax, &c., in forming moulds for casting, are very great where the objects to be repeated are complicated in form. About the beginning of the present century the Germans introduced the use of glue for making moulds, which was not employed in this country until about the year 1826, when Mr. Douglas Fox used it to take casts from his anatomical preparations, calcareous concretions, vegetable preparations, &c., and in order to give greater elasticity to the moulds so obtained, and to keep them in a fit state for use during a long period, he mixed treacle with the glue; this, however, was found to discolour the surface of all white bodies, and its application being limited by this objection, the plan was abandoned.

About the year 1844 attention was again called to this subject by the production in France of a series of casts in imitation of ivory; and about 1846 the Society of Arts of London offered a prize which was awarded to Mr. Franchi for his specimens of casting in plaster composition

in imitation of ivory. At the time the award was made the nature of the material used by him was not known; but it has since proved to be pure gelatine, and owing to the skilful use of his material some exquisite electrotype casts deposited in the Geological Museum were obtained from objects greatly under cost. Mr. Franchi has since found that he can obtain from a gelatine mould a cast in gelatine in relief without losing any of the sharpness of the original. This has enabled him to apply objects modelled on flat surfaces to cylindrical bodies, thus saving the labour and expense of modelling. One great advantage of gelatine moulds is, that casts without seams can be taken from them.

*Diamond Cement*, or white fish-glue, is made of isinglass dissolved in dilute spirits of wine or common gin. The two are mixed in a bottle loosely corked, and gently simmered in a vessel containing boiling water; in about an hour the isinglass will be dissolved, and ready for use. When cold, it should be an opaque, milk-white hard jelly; it is remelted by immersion in warm water, but the cork should be at the same time loosened. After a time a little spirit should be added to replace that lost by evaporation.

#### APPLICATION OF DR. VOGEL'S RECENT DISCOVERY IN PHOTOGRAPHY.

A CORRESPONDENT of the *Scientific American* writes as follows:—"The interest which you and some of your readers take in photography may render the following worthy of note. Dr. Vogel has discovered that a sensitive-eollodion film of iodide of silver, when covered with some colouring matter which obstructs certain rays of light, and does not interfere with other rays, becomes sensitive to those other rays; that is, those rays which are obstructed act photographically upon that film just in proportion as they are obstructed. If the yellow rays are stopped, then the film becomes sensitive to yellow light, and yellow objects, which have heretofore been considered non-actinic, can thus be photographed as easily as blue objects have been. If this be so, then it is one of the most important discoveries that have been made in photography since the discovery of that art. It will enable us to depict objects of all colours, the inability to do which has been a great stumbling block in the way of photography. I need not mention the numerous ways in which it may be applied: suffice it to say that heretofore only one of the four primary colours has been considered to be actinic—that is, the blue. As to the theory of the above, you are well aware that there are two theories regarding the action of light on the sensitive film, one called the chemical, the other the physical theory. In the first it is claimed that the reduction of the silver is done while the light is acting upon the film. In the second it is claimed that a tremulous or vibratory motion is communicated to the film by the vibrations of light; and that when the developing solution is applied, the reduction takes place. In either case it is the vibration of light that does the work. The reason why iodide of silver is more sensitive to the blue ray is, it is thought, that the wave length of that ray coincides more nearly with the size of the particles of the iodide of silver, thereby disturbing or tearing them apart more. If a sensitized iodide of silver film be held before white light, it will be seen that the only colour apparent is the orange; and that blue objects appear black when viewed through it, showing that the blue rays are all obstructed. That film is therefore sensitive to blue light. Again, suppose we give that film a blue colour, then the orange or yellow rays are stopped. As action and reaction are equal, the amount of resistance exerted by the film is equal to the amount of light stopped; and the ray which is then most obstructed has the greatest action on the film. Taking this view of the matter, it seems to me quite reasonable that any ray may be made actinic."

### THE USE OF PORTABLE SCREENS IN PORTRAITURE.

THE use of hand-screens for the purpose of modifying the light and shade in portraiture is much less common than it deserves to be; probably not one professional photographer in a thousand in this country availing himself of its advantages. In the old Daguerreotype days such aids were more commonly used. The late Mr. Claudet was in the habit of using with valuable effect a small black screen at the end of a long rod, for modifying the effects of light upon the model. Much of the effective distribution of shadow in Mrs. Cameron's pictures is said to be due to similar agency, an umbrella or parasol, as it is alleged, occasionally doing duty as a screen. In America, the hand-screen is a recognized adjunct to the portrait studio, more than one ingenious contrivance for the purpose having, we believe, been patented.

The general purpose of the hand-screen is to intercept light and increase shadow, but it may be used to reflect light and decrease shadow. In its simplest form it consists of a screen varying from twelve to twenty-four inches square, or, say, an oval eighteen inches by twelve inches, covered with black velvet, and attached to a handle, say, six feet long. Its use permits the sitter to be placed in the full blaze of a strong light, the incidence of which is modified by the use of the hand-screen skilfully and quietly used by the artist. If the light fall too strongly on the top of a head of glossy hair, making it appear grey; if it fall too strongly on a grey head, making it appear white, the intervention of the screen during part of the sitting at once modifies the result. If a deeper shadow is required on one side of the face or on some portion of the drapery, the screen is brought into requisition, and the shadow secured. If some portion of a light dress is required for pictorial purposes to be kept low in tone; if a vast expanse of white shirt-front threaten to become a mass of chalky white, swallowing up all the other lights in the picture; if some portion of the accessories be too light and obtrusive; if a shadow be desired in the background, the skilful use of the screen will give effect to the aim of the artist using it. Of course it must be used with skill, and a little experience will be necessary to master all its capabilities. It must never come so near the object as to give abrupt effects; it must never be held quite still; care must be used to prevent the shadow extending beyond the desired area. Probably screens of varied sizes would be found useful in securing the best effects. A screen with one white side would undoubtedly be found useful in modifying too deep a shadow on one side of the face, or elsewhere, by throwing a reflected light thereon.

It need hardly be said that one of the most important

points in the use of the screen, demanding skill and judgment, will be to avoid such action as may distract the attention of the sitter. If it be clumsily and injudiciously obtruded, so as to disturb the sitter and cause movement, it would be more mischievous than useful. But this is not necessary: by gentle and quiet action at a sufficient distance from the sitter, a screen may be used so as to scarcely attract attention at all. Many skilled English photographers object to the screens on the score of risk, and reject such aids because they feel confidence in their own ability to secure such light and shade as they desire without the risk of disturbance to the sitter which they conceive the screen involves. In the most skilled hands it is difficult, however, in some studios, without much and constant alteration of blinds and curtains, to get good lighting, and in such cases the screen would be found of great value. In the production of "Rembrandts" the screen is especially useful, and it is in this class of work it is, we believe, largely used in the United States. We recently had occasion, in speaking of a series of American photographs, to especially mention a point in which they excelled, and in which too many English photographers were wanting. In almost every instance the folds and minute markings of the shirt fronts in the portraits of gentlemen were perfectly made in the American photographs, the linen generally being kept considerably in shadow, so as to avoid the shirt being the principal light in the picture; whilst in many English portraits a mass of chalky white linen, with scarcely an indication of fold or texture, rivets the eye before it sees the face. In the old Daguerreotype time to which we have referred, a piece of black cloth was occasionally arranged over the expanse of white linen, and hastily snatched away by a string attached when about half of the time of exposure had elapsed, the aim being to avoid a burnt-out, solarized mass of bluish-white appearing in the picture. This was a troublesome and risky business; for, however impressively the sitter had been warned to sit still and take no notice when the cloth was withdrawn, the sitter was more frequently startled than not, and movement was almost inevitable, at least in the first plate exposed. It is to the skilful use of the hand-screen, we believe, the subdued effect of linen is chiefly due in American pictures; and it is undoubtedly a result worth emulating. We subjoin a diagram and some hints on the

subject which recently appeared in Anthony's *Bulletin* in relation to a screen recently patented, in the United States,

by Carl Meyer. It may be suggestive to those of our readers who wish to avail themselves of such aid; and as the screen is not patented in this country, all the hints are fully at the uncontrolled service of English photographers.

The cut represents Meyer's patent hand-screen and reflector, the latest and best thing out for controlling the light. It is conceded that the use of the common hand-screen in a variety of forms is the best possible method of controlling the light on the subject, permitting, as it does, the placing of the sitter near the middle of the strongest light, thereby shortening the exposure without producing harsh effects. This principle of the screen itself has been long known and used, and is not patentable; but new apparatus for supporting or wielding it is, and the apparatus we would call your attention to is the simplest, cheapest, most convenient, and effective yet invented for supporting a screen or reflector in any possibly required position.

It is made of three walnut sticks, each four feet long. Two of these cross each other to stretch the screen, which is simply fastened by four tacks. The third stick has a metal handle at one end, while the other end is loosely screwed to the crossing of the screen stretcher. Near the handle the staff passes through a universal joint made spherical for symmetry. This completes the attachment. It weighs two and a-half pounds, and when shipped it packs into a bundle four feet long, averaging about one inch thick, and so can be sent cheaply and without fear of breakage. When used, a socket in the sphere fits over the top of any head-rest shaft as a support for the whole. As a preferable support we make a base of metal with column of wood, and shaft of hard wood or gas pipe, adjustable high or low; thus lightening and cheapening it, and making it very difficult to upset, as the weight nearly all lies in the base.

The apparatus is welded by the metal handle, and the peculiar universal joint permits complete revolutions of the screen in any place. The screen also revolves upon the end of the staff, and the staff itself twists in its joint, thus allowing the screen to be placed in any position as freely as if supported by the hand alone. The metal handle serves as a perfect counterpoise, and the slight friction of the parts retain it fixed in any position when the hand lets go. It can instantly be raised or lowered in the column to suit standing or sitting pictures, without carrying it bodily from right to left. It has no machinery about it, no dangling weights, pulleys, or cords to catch. As a reflector alone it is unequalled, and, when inverted, forms a concave reflector by the sagging of the cloth, whereby light may be concentrated upon any spot alone. When used both as screen and reflector, it will correct all the faults of a defective skylight except leaking, and by its finer effects of light can be got more conveniently than is possible in any other way.

*Directions for Use.*—Cross the two light sticks for a screen-stretcher, and at their junction screw the end of the weighted staff. The spherical joint slips over the top of the upright rod of any ordinary head-rest, and screws down, but not so tight as to prevent moving easily. A square yard of cloth may then be attached by four tacks in the ends of the screen-stretcher. Next adjust the weighted staff so as to exactly balance in the spherical joint, and the screen will then be found moveable to any required position, always perfectly poised, and remaining firmly fixed when the handle is released. The screws may be tightened if the apparatus moves too easily. The attachment is welded by the weighted handle, the intention being to control the light by reflecting it on the subject or screening it from too direct light, and any desired effect is instantly attainable. If the apparatus is used solely as a reflector it will save space if the screen-stretcher is attached about fourteen inches from the end of the staff, and the screen itself is loosely stretched so that when the frame-work is presented to the sitter the screen

sags into a concave reflector, to concentrate light on any one point when desirable.

As the result of several years' experience with the screen, we advise the use of paper cambric as not requiring any hem, and cheap enough to throw away when soiled. White softens the light, but does not control it, and is recommended only when it is required to flatten the effect in whole-length figures. Coloured screens, pink or pale yellow, or any non-actinic shade approximating to the colour of freckles, tan, or scars, are influential in lessening retouching on negatives, as the face is lighted all one colour. For a semi-opaque screen or for a reflector this will be found more generally useful than any other.

For perfect control of the light by a screen we recommend the opaque or black screen, when the head or face is the sole object. It is somewhat more difficult to control in the hands of inexperienced or unartistic operators, but the effects are more brilliant, and the requisite softness is obtainable by moving the screen farther from the subject and out of the camera's view.

As a screen over the camera itself it confers all the advantages of the theoretically perfect tunnel light, with none of its defects, thus lighting the subject properly, and shading the camera."

#### THE PRACTICAL PRINTER IN AMERICA.\*

PRINTING has too commonly been regarded amongst photographers as a common-place and easy operation, which might be relegated to the care of boys and girls, with, perhaps, a little supervision from an experienced person; and the skilled printer who devotes himself solely to that branch of the art is rarely as highly remunerated as the equally skilled operator. If the whole art of printing consisted in producing a moderately accurate impression from a negative, and nothing more, nothing would be more simple and easy. But, properly estimated, the business of the printer is something much higher. The skilled printer must be able to produce, not simply the best impression of which a negative is capable, but he must be able to produce, if necessary, a much better picture than any simply printed impression can present. He must not simply be master of the various modes of vignetting and masking to produce various shaped medallions, but he must understand the art of masking, shading, toning-down, and double printing, with a view to artistic effect. He must be master of his methods, so as to produce the varied tones which may be required with certainty and evenness. He must be able to prepare his materials, keep them in order, and recognize and rectify disordered conditions. He must do this with the least possible waste of paper and other material; and he must be able to secure the nearest approximation to permanency which can be hoped for in silver printing on albumenized paper. These are some of the leading qualifications of a printer in an ordinary photographic establishment. If he can print well by development on collodion and paper; print well on plain paper and on opal glass; and has some acquaintance with the various permanent printing processes, so much the better. But it will be admitted that the possession of an approximate mastery of the details we have mentioned involves an amount of accomplishment in the art not usually possessed by boys and girls, and entitles the possessor to a position not in any way inferior to that of skilled hands in any branch of the art.

Notwithstanding the real importance of printing processes, it is curious how comparatively little has been published on the subject. In all manuals it, of course, bears a part, but often a small one; and, with the exception of one or two treatises, no work has been devoted to

\* "The Practical Printer: a Complete Manual of Photographic Printing. By CHARLES W. HARN. Containing Full Details concerning all the Styles and Processes of Plain and Albumen Paper Printing, and of Printing on Porcelain." (Philadelphia: BENJAMIN and WILSON; and London: PIPER and CARTER.)

the subject. In the work before us, however, silver printing and everything connected therewith is treated most exhaustively, and the work is evidently that of a practical man who speaks out of the fulness of his own experience in every branch of regular work, as well as with familiarity of the various forms of fancy printing, which have prevailed more in America than in this country. Mr. Hearn manifestly thoroughly understands his work, and is, moreover, a clear and vigorous writer. As we intend making some copious extracts from this work, with comments and suggestions, we will commence with the author's introductory remarks on the printing room. He says:—

"For good success at printing it is necessary that the printing room should be convenient to work in, and well supplied with those materials, &c., which are so necessary for fine work.

"A good printer, like a good surgeon, may do very well with a few conveniences, but he will more likely do better with more. A good draughtsman may do very well with his pen and parallel rulers, but he can do much better by the use of a set of instruments, and that necessity, a 'T square.'

"The term instruments, in the general sense of the word, is applied to anything by which an effect is brought about, and consequently our printing boards, vignette blocks, &c., are instruments in the case of the photographic printer as well as the case of surgical tools are instruments in the hands of the surgeon. A skilful workman, when once asked, by the foreman of an establishment, what was the instrument he had used to enable him to do his work so nicely, replied: 'My hands are the best instruments I have outside of my brain.'

"So it is with the photographic printer, for his hands are subordinate to that mightier and more valuable instrument, the brain; and consequently a 'thinking man' is far more successful than a merely mechanical one (although the latter may have all the conveniences possible), for 'the brain conceives what the hands execute;' and if a person does not use his brain to good advantage, verily his work will show it.

"Now the whole attention of the brain can be used very advantageously in the printing room of the gallery, as well as in the 'skylight and the dark room.' There is a great mistake often made in the 'fitting out' of a photographic gallery, in placing about all of the money in the 'reception room,' and leaving a few dollars to go into the printing department, and a few more, perhaps, in the dark and operating rooms. A good housewife does not commence at the parlour and furnish down to the kitchen, but she commences first at the culinary department, and after she has furnished that (her work-room), she then commences to furnish her sitting room, and finally her parlour. This is the way it should be with the photographer: he should look first to the skylight and then to the nicely fitting out of this, the operating room, which, of course, includes the cameras, lenses, backgrounds, &c. He then sees to his dark room, and next, but by no means least, he sees to the printing room; and then, finally and lastly, to his reception room, which he furnishes as his means will permit.

"An elegantly furnished reception room does not vouch for good work, although it may indicate that the proprietor had money, or that he had found somebody who would trust.

"A customer, when she wishes her 'likeness taken,' does not look to see if the reception room is nicely furnished, and thus decide as to whether she will be suited or not; not at all—she wishes to see samples of work, and then decides. And since this is so, should we not endeavour to have conveniences, &c., in doing our work, so that the samples and work in general will be excellent, since it is this, and not the elegance of the reception room, that brings in the customers?

— "Another illustration that the elegance of the apart-

ments, &c., is not the criterion by which the customer judges the work of the photographer, is very well illustrated in that of a well-known Parisian gallery, where the patrons of the establishment are obliged to leave their carriages at the entrance of, and walk through, a narrow lane, up three flights of stairs, and directly into the operating room, as the gallery has no reception room whatever worthy of mention. The ladies usually make their engagements through a gentleman friend, and then proceed, all attired, in their carriages to the studio, and are then immediately posed. It may be well to mention here that the patrons are obliged to keep their engagements to within five minutes or so, or they lose their appointment for that day.

"The general opinion among photographers is, that any place will do for a printing room, and it is on this principle that printers are so well known to have very inconvenient rooms, &c., where they almost invariably are obliged to labour under extreme difficulties. Printing rooms should be so arranged that the poor printer will not freeze in the winter nor roast in the summer; and, outside of the printer's own personal comfort, the temperature of the rooms is a matter worthy of the strictest attention on the part of the photographer, or else he cannot expect good work; and if he does expect it, without proper attention being given to the conditions under which the negatives are printed, then he is sure to be disappointed.

"The negatives should no more be printed out of doors in the winter time (more especially if the day is very cold) than they ought to be taken there, posing and all being accomplished, while there is light sufficient to enable the photographer to 'take a picture.' As before said, the fitting out of the printing room is a matter of the utmost importance, and although it has not been recognized by the many photographers, yet it has by the few."

Mr. Hearn then proceeds to describe certain printing and toning rooms in Portland, which he considers models of excellence. In our next we will follow him into some details of practical work.

#### THE TRUTHFULNESS OF PHOTOGRAPHY.

A CURIOUS episode in connection with the Tiebborne case has just been revived in the *Englishman* (a journal conducted by Dr. Kenealy) which closely concerns the trustworthiness of photography as a recorder. It will be remembered that the Lord Chief Justice referred on the bench to the photograph of the "Grotto," which had been produced in evidence, as having been "concocted," and reflecting the highest disgrace on the producer. It transpired about the time that the photographer was Mr. Wyatt, of Fareham, a gentleman, as we then remarked, standing high in his profession as a very skilful photographer. Such a statement from the bench was necessarily of a very damaging character, and the only explanation which at the time appeared was a statement from Mr. Guildford Onslow, to the effect that the photographs presented a perfectly honest transcript of the scene at the time they were taken, which was at the latter end of summer, whilst the Chief Justice had visited it in winter. This was the only vindication Mr. Wyatt received at the time against this painful charge. It appears, however, that Mr. Wyatt at once wrote to his lordship making explanation and protest, and offering to submit the negative for examination; but no notice was taken of his letter in court, nor was any answer received. Under these circumstances Mr. Wyatt forwarded his letters to the *Englishman*, and also sends us copies, which, in vindication of his professional reputation, he asks us to publish. They are as follows:—

"1, West-place, Fareham, Hants., 20th January, 1874.

"My Lord, — May it please your Lordship, in last Wednesday's report of the trial of the Claimant for perjury at the Court of Queen's Bench, your Lordship, in discussing the point about the

'Grotto,' made use of the following remarks respecting the photograph of that place:—'I was never more astonished in my life when I visited the place after having seen the photograph of it. I could not have supposed that the photograph could have so disguised it, and it reflects the highest disgrace and shame on the man who concocted it.' I beg most respectfully to inform your Lordship that I am an artist of many years' standing, and am honoured with the patronage of a large circle of highly-respectable and influential people, whose good opinion I am most anxious to retain and merit.

"With regard to the photograph in question, I can only say that having been requested by Mr. Guildford Onslow, M.P., to visit the 'Grotto,' and take some views of it, I went, accompanied only by my assistant, and after having made a careful survey of the place, I selected those parts which I deemed most suitable to give a correct view of the place.

"My apparatus was of a first-class quality, and I used my best judgment in taking the views, which, notwithstanding the unfavourable state of the weather, I consider successful.

"They were taken in the beginning of September, and consequently would not exactly correspond with the appearance of the place in the month of November.

"However much the severe censure your Lordship passed upon me and my work may tend to injure my character and business, I have the satisfaction of knowing that I did my best by the aid of nature to produce true representations of the object.

"Your Lordship must be aware that a photographer can only falsify by tampering with the negatives; and I am willing to submit them, either for the inspection of your Lordship, or to any experienced artist your Lordship may be pleased to appoint. It is with great timidity I venture to address a gentleman occupying the high position your Lordship does, but I cannot help feeling that the more exalted the station and character of the censor, the deeper must be the wound to my personal feelings, and the more serious injury to my moral and professional character.—Awaiting your Lordship's reply, I have the honour to be, my Lord, your Lordship's most humble and obedient servant,

"ARTHUR WYATT.

"Lord Chief Justice Cockburn, Queen's Bench, Westminster."

"1, West Place, Fareham, Hants.

"21st February, 1874.

"MY LORD,—May it please your Lordship: Being desirous of showing your Lordship the marked difference in the 'Grotto' now, and when I photographed it in September last, I have within the last ten days attended at the spot, and, with the permission of the tenant, taken another photograph of it from the same point as the one taken in September, both of which I now take the liberty of forwarding for your Lordship's inspection. I would also take the liberty of informing your Lordship that one reason of the marked difference is, as I was informed by the tenant of the mill, on account of a number of sheep being in the Grotto several days since the first photograph was taken.—I have the honour to be, my Lord, your Lordship's most humble and obedient servant,

"ARTHUR WYATT.

"The Lord Chief Justice of England, Sir Alexander Cockburn, Bart., Queen's Bench, Westminster."

It is quite beyond our province to enter into comment of any kind upon the trial in question, or any of its incidents; but it is impossible not to sympathize with Mr. Wyatt in his mortification on receiving a public censure without the means of equally public explanation and vindication. The *Englishman* regards it as a flagrant example of conscious and intentional injustice—a view of the case which can scarcely afford Mr. Wyatt any satisfaction. Whilst in justice to Mr. Wyatt, if not of vital importance to justice in the case, it would have been desirable that some publicity should have been given to the letters in court, it should be borne in mind that the judges were at the time inundated with letters on the case, the majority of which were, if we remember rightly, as announced from the bench, put aside unopened, attempts to influence the court by indirect evidence or argument being very properly resisted. We cannot with certainty indicate the best or proper mode which should have been adopted by Mr. Wyatt to set himself right; but it is probable that he ought to have communicated with the counsel for the defence, who could have brought the matter before the court in due course. At any rate, we apprehend that pub-

lication of his letters now vindicates Mr. Wyatt from the charge of either bad faith or incapacity in the eyes of his patrons and professional brethren.

PORTABLE TENT.

BY J. H. B.

AFTER many trials in making tents for the wet process in the field, I have fixed upon one which I have found most efficient and convenient, and which in the minor details of construction, I think, possesses some novelties. It consists of four upright poles (*a b c d*, fig. 1) 6 feet 6 inches high, made of deal one inch square, and rounded towards the ends, upon each of which a brass ferrule is placed. The two poles on each side of the tent (*a b* and *c d*) are con-

Fig. 1. Fig. 2. Fig. 3.

Fig. 1 shows the poles and table without the cords and covering; fig. 2, two poles (*a* and *b*) as placed for packing; fig. 3, the tent ready for use, two of the cords not being shown.

needed by crosspieces (*e* and *f*) 2 feet 6 inches long, 1½ inch deep, and ½-inch thick, hinged in the middle, and working on pivots at each end, so that the two poles may lie close together for packing (*vide* fig. 2, which shows them slightly separated.)

When the tent is erected, these crosspieces are on the inner sides of the poles, and upon them the table (*t*), consisting of three half-inch boards 2 ft. 6 in. long and 6 in. wide, tongued and grooved and hinged together so as to fold up, rests. The table is retained in its position by a small stud entering each of the poles (*b* and *d*) about a quarter of an inch, and a hook and eye at each of its other corners, thus having the effect of rendering the joints in the crosspieces (*e* and *f*) rigid. Two straps (*g g*) nailed on these latter, near the hinges, and to the upper parts of the adjoining poles, assist in bearing the weight of the table, and easing the strain upon the hinged joints. The cover of the tent, which is made of black calico lined with yellow, and which reaches down to the ground, is fixed to the poles, and is never taken off. Thus the whole arrangement consists of only two parts, the tent and the table. To the top of each pole a light cord is fixed (outside the covering, of course) of suitable length, and having the usual means for tightening each cord, instead of going round a notch in the wooden peg by which it is secured to the ground, passes through a hole in it, which prevents the peg from becoming detached and lost, and keeps each on its proper cord ready for driving in. A glass window (not seen in figures) three inches wide and eight inches high, having a wooden shutter, and capable of being opened to admit air, is inserted in a light wooden frame let into the calico just above the operating table. On the left side (*a b*), just below the crosspiece, is another window formed of yellow calico. At this window the development is performed, the operator sitting on a box, stone, or other temporary support, and all washings and spillings going on to the ground. By a simple arrangement of double curtains along the side (*a c*) a door is formed, which is perfectly secure against the admission of light; and a piece of

coarse canvas, six inches wide, sewn along the bottom of the calico, covering and lying close on the uneven ground excludes all light from that quarter, stones or other weights being put on if necessary.

This tent will stand almost any amount of wind, and is extremely roomy and convenient to work in, and I have used it successfully with the thermometer at  $115^{\circ}$  in the shade, generally leaving the window and door open on going out.

To erect the tent, drive in the two pegs belonging to poles *b* and *d* as nearly as you can guess in their proper places. Raise the tent up by holding *b* and *d* in the hands inside the covering; then stretch out the crosspieces, and when the covering is tight on the three sides, *ab*, *bd*, and *dc*, and the interval between *a* and *c* is equal to *bd*, push the poles down, so that the short pins which are at the bottom of the poles shall just enter the ground. By laying hold of one of the two remaining cords, the tent will be kept in its position while a third peg is driven in and its cord tightened; and the fourth will render the whole secure. Now put the table in its place, and fix it with the hooks and eyes. Five minutes is ample time to do all this, and two minutes for taking the tent down and rolling and tying it up, for which latter purpose the stretching cords are used.

In travelling, the tent and tripod legs, which are nearly as long as the tent poles (so that the camera may be placed on a level of the eye of a person standing), are made up with the table in one package, which is light enough to be carried by a small boy. Instead of the table of boards, a box with divisions for the various bottles, &c., might be substituted, and would save trouble in packing.

#### NOTE ON THE MEASUREMENT OF THE CHEMICAL ACTION OF SOLAR LIGHT.

BY DR. T. L. PHIPSON, F.C.S., ETC.\*

THE method employed by Messrs. Bunsen and Roscoe having been recently called in question, as leading to an exaggerated conception of the amount of chemical energy in the solar rays, Marehand† has had recourse to an apparatus which is merely a modification of that invented in 1859 by my lamented friend Niépce de St. Victor. In this apparatus light acts upon a solution of ferric chloride containing an excess of oxalic acid, and the chemical intensity is measured by the volume of carbonic acid evolved.

Many years ago I made some experiments on this subject in Paris, and described a method‡ which I believe capable of giving more accurate results than any hitherto obtained. Having discovered that a colourless solution of molybdate of ammonia in sulphuric acid became greenish blue when exposed to the sun, and colourless again during the night, and that the amount of chemical action exerted to produce this tint may be accurately determined by a dilute solution of permanganate of potash, it suffices to operate always upon the same quantity of substance, and to expose it to the light for the same period of time, and in every respect in the same conditions, in order to possess a perfectly accurate process by means of which the problem of the chemical intensity of solar light may some day be solved in a completely satisfactory manner.

#### ECONOMY IN PRINTING.

BY J. H. B.

IN printing large numbers from the same negative, the following plan is not without advantage as saving both time and materials, and making all the copies exactly alike. Having determined upon the exact shape and size of the finished photograph, as well as the parts of the

negative to be included, cut out with precision, in thin paper, an opening of the same size and form, place this on the face of the negative in the required position, taking care that the vertical lines of the picture are parallel with the sides of the opening, and fix it there by sticking it to the face, or, turning it down, to the edge or back, with gum or bee's wax (preferably the latter, as it does not wrinkle the paper). Sensitize the positive paper in sheets of the largest size convenient, and, having marked it off in pencil on the back into pieces of the exact size of the opening in the mask, cut them out with a sharp knife on a strip of glass. In printing, each piece is laid in the opening of the mask, and exposed as usual.

By this method the least possible quantities of paper, sensitizer, and other solutions are expended; each print is most accurately and neatly cut, ready for mounting; all the copies take in exactly the same parts of the negative; and the uprightness of the vertical lines is easily preserved. Oval, circular, or vignette pictures may be done by the same means.

### Correspondence.

#### BEER FOR DRY PLATES.

SIR,—I thank you for your courteous notice of my communication regarding Captain Abney's beer process. I fully concur in your remarks respecting the difficulty of obtaining, in many cases, accurate formulæ; but, with regard to the beer, permit me to say that I believe it to be a great element of success in this process—so far, at least, as *rapidity* is concerned—for the following reasons.

My first experiment was made with some of Whitbread's bottled ale, and I obtained successful negatives, giving the brown colour stated by Captain Abney to be the result of "proper exposure and good manipulation;" but these plates received six times the exposure necessary for wet negatives.

My next experiment was made with some beer brewed at Newport, the water for which is drawn from Carisbrooke, and is identical with that in the celebrated well within the castle. These plates required double the exposure of those above referred to, and the colour was of an indefinable kind of deep green—very excellent, however, for printing purposes.

My third trial was made with some Shanklin beer, and the result was unsatisfactory, the deposit being of a blue-black colour.

My fourth experiment was conducted with what is known as "Anglo-Bavarian" ale—very excellent for drinking purposes, but totally useless (to me, at least) for dry plate work. I failed with this beer to start with, but I attributed my failure to other causes, until I had closed up every avenue of escape from my dilemma but the beer, which I at last proved to be altogether unsuitable for the process. Out of twenty-four plates prepared for the express purpose of testing this particular beer, I did not obtain a single negative that was not fogged, dirty, and insensitive; fabulous exposures in bright sunlight failed to give detail, even in the high lights. I have ascertained that this ale is brewed at Shepton-Mallet, in Somersetshire, and it is possible that the water is not suitable for photographic purposes.

It was for the above reasons that I wished to ascertain what kind of beer Captain Abney had found to be the best, and it would be interesting to know if he has experienced any such difficulties or failures as I have detailed, as I feel sure that the beer has a great deal to do with success in his process.

I would, in conclusion, beg to refer to an excellent article in the present YEAR-BOOK, by Mr. P. Le Neve Foster, in which, referring to want of accuracy in description, he very truly remarks that "from want of attention to this

\* *Chemical News*.

† *Marchand, Journ. de Chim. et Phar.* [4], xviii. page 417, 1873.

‡ *Phipson, Comptes Rendus, Paris, 1863.*

point, it frequently happens that the whole value of the communication is lost."—I am, sir, your obliged servant,  
July 27th.  
D.R. PROCESS.

[As we have said before, the most precise statement of formulæ which can be given is always desirable; but we fear that the interesting statement of our correspondent's experience regarding beer furnishes evidence rather than the advantages of the beer process must be confined to photographers residing in certain districts, than that the formula was faulty. Supposed Captain Abney had said pale ale from a Rochester brewery, or from the canteen at Chatham, the statement, though precise, could not have been of much value, as photographers generally could scarcely have obtained the same sample.—Ed.]

COMBINATION PRINTING.

SIR,—My way of combination printing, in which the conditions laid down by Mr. Tilley can be fulfilled, is as follows.

Take the portrait on a white background, and make duplicate register marks on both portrait and background negatives, at the two bottom corners, like a capital L. Place the view negative over the portrait negative so that the register marks coincide, and paint out the figure with black varnish, keeping within, rather than without, the outline, after Mr. Bovey's manner. The edge may be softened more, where required, by partially wiping the edge while wet. When dry, it may be further amended, where the hard cutting lines come, with a penknife, the blocking out being on the back of the negative. Print the portrait in the usual way, only have the paper a little longer at the bottom of the print. Now take the print and register it with the L-shaped marks on the view negative; turn the bottom edge of the print round the bottom of the view negative, and fasten with a little gum, to keep it in register. It may now be printed in an ordinary printing frame. If carefully done, no join will be seen.

I may say, in case of a profile face on a black background, the background negative will require touching on the face-side also, down the face; but this will scarcely be required in the hands of a careful printer.

I claim that my system is much quicker than Mr. Bovey's when more than one print is required, and equal to Mr. Tilley's, if not the same.—Yours respectfully,  
HENRY GREGGON.

THE SENSITIVE GELATINE PELLICLE.

SIR,—On comparing my letter to you with Mr. Kennett's answer, it struck me that Mr. Kennett's pellicle must indeed be sensitive, and I do not wonder if others have found a difficulty in that respect.

Grammar says, two negatives make a positive; I will endeavour in this case to make two positives create a negative, so I will try again, and send you the result.

I beg to assure Mr. Kennett that the case containing the pellicle sent to me was wrapped up in one "scanty covering of white paper."

I tested his preparation on plates dried spontaneously, as well as dried on a tin containing a little water of about 120 degrees. Mr. Kennett seems to know the result I wrote about well; his description of the film *bursting up* hits it off to a nicety.

As regards my duty, I considered it solely as due to myself to test a process so much wanted, and described as so certain. I shall be glad to hear from your columns of the success of others who have tried it; hitherto I have only seen accounts of failures, which, from Mr. Kennett's letter, seem numerous. Perhaps his success is due to some little omission accidentally made in his instructions.

I beg to assure Mr. Kennett that I had not the slightest idea of running down his sensitive pellicle when I wrote, and only did so in the hopes of eliciting the experience

of others, as suggested by you, Mr. Editor, in your columns.

Did I not live so far from London it would give me the greatest pleasure to call on Mr. Kennett to express personally my regret for ruffling him, and to gain experience in delicately handling his sensitive pellicle.—I am, Mr. Editor, yours faithfully,  
28th July.  
W. J. C. M.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The members of the South London Photographic Society met on Saturday last at St. Peter's Rectory, Walworth, to partake of the graceful and kindly hospitality to which the Rev. F. F. Statham, M.A., President of the Society, in accordance with his annual custom, invited them. The occasion was, as usual, one of unmixed enjoyment to all present.

TRAMPS IN THE TYROL.—Those of our readers who contemplate a few weeks' holiday ramble cannot do better than obtain "Tramps in Tyrol," by a gentleman whose name is well known to them—Mr. H. Baden Pritchard. The volume contains the adventures of the author and three travelling companions, who rambled in their own fashion somewhat out of the beaten track untrammelled by conventional rule as to route or transit. To those who can secure the time, nothing can exceed the delights of such pedestrian experience. Mr. Pritchard's volume is something considerably more than a guide-book; it is a pleasant, genial companion, as full of interest and fun as it is of information. The photographer will have only one regret on reading it, namely, that details are lacking as to the experiences with the pocket camera and dry plates which the author so successfully employed. There are a couple of capital illustrative vignettes and frontispiece by Mr. John Proctor.

ROYAL PHOTOGRAPHY.—We learn from the *Standard* that "the two eldest sons of His Royal Highness the Prince of Wales—Prince Edward and Prince George—honoured Mr. Melhuish with sittings for their portraits on Monday last, at his studio, York Place, Portman Square."

SANITARY HINTS.—It will interest many of our readers to know that the publishers of this journal have reprinted in the form of a small twopenny pamphlet the "Sanitary Hints for Photographers," by Dr. Napier, which we recently published. The information on the subject generally, and especially on poisoning by photographic chemicals, and the suitable antidotes, is so valuable and important, that every photographer ought to have the work at hand for immediate reference in case of accident.

SOLAR PHOTOGRAPHY.—Dr. Sellack, of the Cordoba Observatory, has been experimenting on photographing the solar prominences without a spectroscope. He absorbs the violet rays of the sun's image by interposing an iodide of silver film, and then seeks to obtain an image on iodised collodion, which is sensitive only to the violet and indigo rays. The image will thus be formed by that portion of the spectrum which can pass through the film and act on the collodion. He has not yet succeeded in obtaining a decisive result.—*English Mechanic*.

EXHIBITING PHOTOGRAPHS.—The *Scientific American* says:—"The effect of photographic transparencies in the microscope, as well as on the screen, is greatly improved by placing a pale blue glass in the path of the illuminating beam. This corrects the brown or 'foxy' tone which they too often present, and gives depth and richness to the shadows."

A TIGHT BATH-HOLDER.—Mr. L. A. Deromo, writing to *Anthony's Bulletin*, gives the following hints:—"Porcelain bath-holders, as many may have experienced to their loss, are very bad receptacles for the silver solution. For my part, I have found but one out of a number I have which could hold the silver without broaking. Every now and then I had to scrape off the crystals which formed on the outside of these sieve-like holders; and the inside lowered and lowered incessantly, to my loss. I painted, varnished, shellacked some of them; but no go; out the silver went. So at last I devised the following method, which beats all:—Make a tight box of good wood, one-quarter of an inch thick, to fit on your bath, but leaving a quarter of an inch space between the porcelain and wood all around and under. Glue, inside and on the bottom, a few small cones of wood, so that the least surface comes in

contact with the bath. Now warm your porcelain, wipo it clean, slip it into the box, and pour between the two pretty hot beeswax to which you may add a little resin and turpentine. Set aside to cool. Your bath will be then much better than a new one."

**MAKING CHLORIDE OF GOLD.**—Mr. H. J. Newton, referring to his method of preparing chloride of gold from coin, says:—"I take 2 drachms of nitric acid and 3 drachms of hydrochloric acid; in that I dissolve a five-dollar gold piece (equivalent to a sovereign). That is pure enough; the copper is an advantage rather than a detriment. In this way you have 135 grains of gold. Reduce that so as to have 8 grains of gold to the ounce, or 1 grain to each drachm, and you will always know when you pour it out how much you have. That will give you about 16 or 17 fluid ounces to a five-dollar gold piece. That will keep. You may put in salt if you choose; I sometimes do that. This solution will go farther than any you buy. A few hours before you use it, neutralize it with bicarbonate of soda, borax, or any of the alkalies, according to the tone you desire. Bicarbonate of soda will give you a brown tone, and borax a black. Make it up a few hours before you want to use it, so that it will turn litmus paper blue, and I do not believe you can prepare gold to make better tones. When you make this solution it is acid, but you can neutralize it with bicarbonate of soda down to the point where a drop of it will turn green, or you can make it perfectly neutral, and add a little *agua regia*."

**CHEMICAL ACTION OF SOLAR RAYS.**—The notion that chemical action is not confined to the blue ray, suggested by Sir John Herschel, and since elaborated by Professor Draper and illustrated by Dr. Vogel, seems to be gradually gaining ground. In a review by Arthur Schuster, in *Nature*, of a work on the "Science of Painting," by Professor Von Bezold, we find the following:—"In his account of the elementary principles of optics the author abandons the old method of dividing vibrations into heat rays, light rays, and actinic rays. We note this point as it is one which must soon play an important part in physics, and will doubtless provoke much discussion. The author seems to prefer the following method of viewing the facts to the old one:—A body absorbs a certain class of rays peculiar to itself; whether these rays are converted into heat or into chemically active rays depends upon the peculiar properties of the body. In order, however, to include in this statement all the facts included in the old division, we must add that, as a rule, bodies absorbing the ultra-violet rays are thereby rendered more chemically active; and, as a rule, bodies absorbing the red are thereby heated. This method of looking at the matter seems to us to be the one most closely agreeing with the facts. Prof. von Bezold gives, as a proof that the red rays may be chemically active, the fact that, as the green colouring matter of leaves absorbs the red end of the spectrum, as well as the blue, the red rays alone are sufficient to sustain life in the plant. He might have referred to the recent discovery of Vogel, who photographed the red end of the spectrum by mixing a red colouring matter with bromide of silver; and, on the other hand, to the fact observed by Budde, that chlorine is heated by the ultra-violet rays."

**TRANSPARENT GUM.**—A little glycerine added to gum or glue is a great improvement, as it prevents the gum or glue becoming brittle. It also prevents gummed labels from having a tendency to curl up when being written on.

**TO IMPROVE THE ADHESION OF GUM ARABIC.**—It is a well-known fact that gum arabic will not cause some kinds of blotting paper to adhere. This may be remedied by adding, to eight ounces of the concentrated solution, sixteen grains of aluminium sulphate. Alum answers also, but not so well.

## To Correspondents.

**TWIN.**—If you had stated details of your operations, we might probably have been able to indicate at what point you probably fail; but when you say you enlarge in the copying camera in "the usual manner," you afford no clue to the failure. There are half-a-dozen or more usual manners. As your picture is too dark with the fullest exposure and shortest development, try a shorter exposure and short development. Are you sure that no light reaches the plate except that which passes through the negative? Do you develop with pyrogallie acid or iron? The former is preferable, and you may probably, in any case, increase the proportion of acid in the developer.

**IGNORAMUS.**—There is no work on the production of photographic transparencies; but many articles on the subject have appeared in the PHOTOGRAPHIC NEWS, and in the various issues of the YEAR-BOOK OF PHOTOGRAPHY. If you state with which process you are most familiar—whether with the wet process or dry processes, and if the latter, which of them—we can probably give you some hints as to the best mode of proceeding.

**T. H. C.**—Your question is scarcely clear. You ask which is the quickest dry process, and then proceed to refer to commercial dry plates, leaving us in doubt as to which subject your question refers. One of the quickest dry processes which has been published is the urano-bromide process as described by Col. Stuart Wortley; but it requires skill and experience to work it successfully. The morphia process is quick; so is the beer and albumen process of Captain Abney. The gum-gallic process, with strong alkaline development, is very quick. As for the quickest dry plates sold commercially, we cannot say which is quickest. The Wortley plates, the Russell plates, the quick Liverpool plates, and the quick Hill Norris plates, all have claims, and we cannot undertake to determine their legitimate precedence.

**AMATEUR.**—On the whole, dilute albumen is better than gum for applying to the negative film before varnishing, as being less liable to crack. 2. Yes. 3. Albumen and water alone. Carbolic acid might be added if you wish to keep the solution ready for use.

**WM. STURGEON.**—The address of Messrs. Trapp and Co. is, 1, Budge Row, Cannon Street.

**PHOTO. C. B.**—The probable cause of your silver bath becoming turbid or "milky" after the immersion of a few plates is that it is already over-iodized, and the additional iodide left by a few plates supersaturates the solution, leaving the particles floating, which cannot be dissolved. You used double the proportion of iodide of potassium in iodizing the bath which we should have deemed necessary. In hot weather the silver bath will hold less iodide in solution than in cold weather. Try a portion of the solution—say five ounces—pouring it slowly into five ounces of distilled water. You will probably find it become turbid at once. This will indicate excess of iodide. You may then make up the solution to the proper strength by adding nitrate of silver. If this experiment prove successful you will know what to do with the rest.

**QUERIST.**—We know very little of the subject. We believe there are various colleges on the Continent which grant degrees in absence on the forwarding of certain certificates and payment of certain fees; and, for anything we know, there may be similar institutions in America. But we are not familiar with the subject. Our own honorary degree was granted under very gratifying conditions, being at once unsolicited and unexpected, and without the payment of fees or cost of a farthing for any purpose. We, of course, should never dream of noticing the remarks in question, the animus of which is apparent to everyone, as is also the curious ignorance on the subject which characterizes it.

**DEVON.**—Varnishing a transparency need not spoil it, nor need it necessarily injure it, if the varnishing be carefully done. If the transparencies are produced on wet plates in the camera, they can of course be produced reversed to meet the contingency you mention.

**C. A. OWEN.**—We cannot with propriety recommend lenses by name in this column. If you will send us the list of second-hand lenses again, appending a number to each, we can then indicate by its number which is most likely to answer your purpose. The fourth on your list seems most likely for the work you mention.

**R. J. T.**—We have obtained almost all kinds of tones from the sensitive paper you name; but we have noticed that it has a little tendency to become warm in the hypo bath unless toning is carried apparently a little too far in the gold bath. 2. So far as we know, yes.

**REDWORTH.**—We cannot tell you where you can purchase background negatives suitable for combination printing; but it is probable that a single advertisement in our business columns, announcing your want, and describing the special character of negative you require, would secure you offers at once.

**R. D. L.**—Some of the wide-angle lenses will include an angle of 90°; but, except for special purposes, this is much more than is desirable. About 50° is sufficient for most purposes. When the size of the picture is the same as the focal length of the lens, an angle of little over 50° is included. 2. The sky of a negative should not be quite black and opaque; if it print with a slight tint, a much more atmospheric effect is secured.

**D. G.**—No announcement has yet been made as to the time or place of the exhibition.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. NOT SO EASY AS IT LOOKS—ARTIFICIAL ILLUMINATION— A WORD IN SEASON.

*Not so Easy as it Looks.*—It is very strange that, notwithstanding the many kinds of dry plates purchasable at every dealer's, and the sensitive gelatine pellicle now to be obtained, and the many new formulæ that have been published for rapid development and for preserving plates *ad infinitum*, there is no startling increase in the number of pretty pictures produced nowadays. It would seem as if, after all, something more is necessary than merely buying a packet of plates over the counter, and emptying them one by one into the "machine," and taking them out again, exactly in the same way as you would a packet of Horniman's pure tea, which must not be opened before use. You put in plates, and you take out pictures without even so much as turning a handle; and if the pictures are not pretty ones, then the fault is due obviously to the goods inside the packet, and they must be bought elsewhere in future. We fear there are many who think that now so much has been done for them in surmounting difficulties at the outset of the work, that there remains nothing further to do, and that any one may become a photographer. They will be grievously disappointed at the very first trial. You may buy films as clear and sensitive as possible, and yet be unable to get a picture in any way presentable, although the exposure has been well timed, and the camera adjusted under guidance of an artistic eye. One must serve some sort of apprenticeship to a process before it can be thoroughly understood, for breaking open one of the yellow packets, and experimenting with half a dozen plates with developers of different kinds, does not teach much. The photographer is so closely connected individually with his work, that he must perforce learn something about the nature of it to begin with. We are not talking here, of course, of skilful photographers who have worked for years at different processes, for with them success is readily obtained whatever they may attempt. But an amateur who has worked the wet process with tolerable success, by paying care and attention to his work, will find that although some of his troubles may be removed by having recourse to dry plates, there is still very much to be done in the matter before he secures good pictures regularly. It is for this reason that people succeed with one dry process and not with another. The method they have elaborated themselves, and, therefore, know most about, they can work well with; but let them take up a new and strange process, and they begin to grumble. The fact is, they do not give the new films the same fair treatment that they bestow upon their own pet plates. Most of the numberless dry plate methods that have been proposed from time to time will yield good results, if only the operator will give himself the trouble to go into them thoroughly. Witness the comparative results obtained by Russell Manners Gordon some time ago. This *facile princeps* of dry plate photographers undertook to make a trial of half a dozen different processes, and promised to exhibit the several results at the exhibition of the Photographic Society. When the time came, there were half a dozen pretty bijou views, such as only a Gordon could produce, each one outrivalling the other for delicacy, and every one representing a different process. A better proof could not be given that most dry plate processes will give good results, if only thoroughly understood by the operator who uses them, although, of course, some films are more rapid and simpler in manipulation than others.

*Artificial Illumination.*—Another proposal has been brought forward to obtain a brilliant artificial light. It will be remembered that three years ago Dr. Van Monckhoven read a paper at the Photographic Society of London on the subject of photographic enlargements, and called

attention to the various methods at one's disposal for producing brilliant illumination by artificial means. He directed currents of oxygen and hydrogen upon a pillar compounded of carbonate of lime and magnesia, instead of employing a cylinder of lime only, and in this way increased to a notable degree the already very powerful light of the oxyhydrogen lamp. He also employed at times, when hydrogen was not forthcoming, a spirit lamp of special construction, directing a jet of oxygen through the spirit flame. A slight modification of this light is now proposed by M. Hannecker, which has, it is said, the effect of rendering the light more brilliant still; and if such is really the case, the suggestion is of considerable value to those photographers who employ an oxyhydrogen lamp for enlargement in the winter time. Herr Hannecker makes his cylinder of a compound of carbonate of lime, magnesia, and olivine, the materials being compressed by means of hydraulic pressure. Olivine is a native silicate of magnesia.

*A Word in Season.*—It is well to bear in mind, during the hot weather, the boiling points of the two solvents in collodion, alcohol and ether. The former boils at 173° Fahr., and the latter 96° or 97°. A mixture of the two in equal parts does not give a mean boiling point between these two, for if you heat such a liquid gradually, the ether evaporates first of all, and then the alcohol; but the alcohol, nevertheless, especially when added in large quantities, retards to some degree the evaporation of the ether, and for this reason, as also from the fact that alcohol is much slower in vaporising, photographers should employ a maximum amount of alcohol in their collodion in the summer season. During the past fortnight great care has been necessary in coating large plates evenly, by reason of the rapid setting of the collodion, and the only thing to be done is to add an unusual dose of alcohol. Keeping the stock of plates in a cold dark room, and coating them there, is a better plan still, if one happens to possess such a luxury, for the condensation of moisture afterwards upon the back of the sensitized plate only tends to keep it moist a little while longer.

### FRENCH CORRESPONDENCE.

#### TEMPERING THE HEAT OF THE STUDIO—PRINTING WITH GREASY INK—COAGULATED ALBUMENIZED PAPER—NITRATE OF POTASH IN THE SILVER BATH—WET PLATE PHOTOGRAPHY WITHOUT A DARK TENT.

In a letter which has just reached me from a provincial photographer, M. Malbret, that gentleman describes a method which he employs successfully in keeping out the excessive heat from his studio, without at the same time interfering with its illumination. The studio, which is eight metres long and three and a half broad, is constructed upon the roof, quite isolated from adjacent buildings. It is not, therefore, in any way protected from the sun except by means of a simple shutter; the glass roof above receiving the sun's rays directly upon it, it is by no means surprising that the temperature often passes above 45° Centigrade. The photographer is compelled at times to suspend work altogether, notwithstanding the establishment of free currents of air throughout the place.

To remedy these grave inconveniences, M. Malbret has covered the upper part of his glass for the whole length of the studio; and at a distance of eighty centimetres from the roof (so as to let the air pass freely), he has constructed a kind of tent, which can be extended and shut up, at will, by the aid of a very simple mechanical contrivance. With this M. Malbret can work at his ease throughout the day in a temperature scarcely more elevated than that out of doors in the shade.

What is remarkable in the matter is, that although the studio is thus entirely covered in with ground glass and a lining of fabric, the exposure required is not longer. The space left between the glass and the tent allows the light to circulate in the same way as the air; but if an instan-

taneous portrait is required—in the case of a child, for instance—it is only necessary to draw back the curtains for a moment to secure a larger quantity of light.

I have received from M. Marzocchini a series of photographic impressions reproduced from clichés obtained from sketches, and taken from nature direct, which are of a most interesting nature. They are examples of a process which M. Marzocchini is working commercially, the pictures being, in fact, portions of a work entitled "Album Livornese." They prove that we have to record still another success in the matter of printing with greasy ink.

M. Herbert père has addressed a few observations to me with respect to the communications of MM. Quiquerez et Therré fils, about the coagulation of albumen, which I have already alluded to in my previous letters to the PHOTOGRAPHIC NEWS. M. Herbert thinks, with M. Quiquerez, that dried albumen coagulates with much more difficulty than when in a liquid condition. He also doubts the inefficacy of dilute alcohol; but he differs from M. Quiquerez on the point of coagulating the albumen first of all by the aid of concentrated alcohol, for, according to him, if M. Quiquerez has not obtained complete coagulation, it is simply because he has not allowed the action to continue for a sufficiently long time. At the same time, M. Herbert regrets the employment of alcohol in this connection, for it is far from being an economical substance to use. He thinks that its cost would outweigh any saving of nitrate of silver that might be effected.

M. Herbert has often made experiments with wet bath to which nitrate of potash has been added, without obtaining the good results alluded to by M. Quiquerez. To find out something of the rôle played by the nitrate of potash, he placed a piece of albumenized paper upon a saturated solution of this salt, and two minutes were quite sufficient to dissolve away the albumen from the surface.

In conclusion, M. Herbert says that all the methods proposed for coagulating albumen only jeopardise the most precious qualities of the paper. One sole means has been completely successful in his hands, but he reserves the details of it for the present, merely forwarding a sample of paper prepared by his process, with a request that it may be experimented with. I send you a portion of it to try, merely quoting the advice of my correspondent, which is to the effect that it should not be toned in an acid bath, nor in one too much charged with chloride of gold.

Apparatus for working the wet process without a tent or dark box of any kind are as numerous in France as in other countries, and, notwithstanding the success attending the employment of dry plates, they are still much used. Nearly all of the arrangements resemble each other, but there are some which are more practical than others. Last week I had occasion to experiment with an apparatus which is of a most simple, ingenious, and handy character, designed by a Parisian photographer—M. T. Valette. Its dimensions were represented by a cube of twenty-five centimetres, so that it is handy to carry about, while its weight, with all its accessories, does not exceed ten pounds. The lens, six plates, four baths, bottles, &c., find room within this limited space. Placed upon its stand, which is itself very light, the apparatus represents two boxes superposed on one another; that above is the bellows camera, while the lower one is the laboratory or dark room. The latter encloses the four vertical baths placed beside one another. At the moment of operating, the bottles, placed in a little cupboard at the side, are taken out, and into the first bath is poured nitrate of silver, into the second the developer (pyrogallol solution), into the third distilled water, and into the fourth a sulphocyanide fixing solution. The camera slides by means of a groove upon the laboratory box. The object is focussed in the ordinary manner, and then the plate is collodionized and introduced into the frame in place of the ground glass. This frame is made to descend rapidly (as soon as a string is detached which keeps it in its place) into the compartment below, where

it becomes immersed into bath No. 1, containing the silver bath. After sojourning therein for about two minutes, during which time you take care to move the plate continually up and down, it is drawn up into its proper place again by the aid of the string alluded to. The exposure then takes place, and as soon as this is completed, and the lens capped, then the portion of the camera carrying the frame is advanced as far as the first groove indicated, and corresponding exactly to the spot where below is to be found the bath containing the developer. The exposed plate is let down into it in the same way as before, and after a couple of minutes it is lifted back again to its place in the camera, and the frame is again shifted until a second groove is reached, and the plate then descends again, this time being dipped into a bath of distilled water, where it is kept in motion for some time, in order that it may be well washed. The plate is subsequently introduced in like manner into the fixing bath. After the fixing has been completed—in case there is no convenient spot near to wash the plate—it is again put into the distilled water bath. The only precautions to be taken in making use of this apparatus consist—

1. Before operating a second time, the frame itself must be plunged into water, and then well drained, and care must be taken that there is no water attaching to it when it is again put into the silver bath.

2. The dark cloth which serves for focussing must be kept in front of the instrument during the various operations, especially if the apparatus happens to be standing in the sunshine.

The bath must, of course, be filtered and strengthened at the end of the day's work when the photographer gets home. After it has served for the production of eight or ten clichés, the developer should be thrown away, and replaced by a fresh solution; and the same holds good with the bath of distilled water. The finished negatives are put into a grooved box, which forms part of the lower portion of the apparatus, and which contains room for as many plates as are necessary for the day's work. All the photographer's baggage is thus enclosed in a small volume, the dimensions of which we have already given. By its aid we have produced several pictures from our window, looking out upon the Avenue de l'Imperatrice, near the Arc de Triomphe and Bois de Boulogne. All the plates succeeded very well, and we are glad to bear witness to the compact and handy nature of the little apparatus, the price of which, by the way, is relatively a most moderate one. It forms a very convenient instrument for amateurs, and for tourists especially.

M. Valette has written a little pamphlet, which accompanies the instrument, and which explains the method of working, the simple formulæ employed, &c., forming, therefore, a neat practical little manual.

ERNEST LACAN.

#### PRINTS FOR COLOURING.

PERHAPS no subject has received less attention from photographers than the production of the plain prints intended to be placed in the hands of the artist for colouring. Of course, every portraitist in whose establishment first-class work is executed aims to produce such prints as will best suit the style of finishing it is to receive, or as his especial artist may desire. But the especial fitness of prints for different styles of colouring has been rarely discussed or considered, and in too many cases a general impression prevails that defects may pass in prints for colouring which would be fatal in work intended for issue as plain prints, the skill of the artist being trusted for remedying all blemishes. An exhaustive paper appeared in a recent number of our Philadelphia contemporary, by M. Costelle Edgerley, in which this subject is very fully treated, and much excellent advice and suggestive information given. After dwelling upon the difficulties of the artist in dealing with unsuitable prints, and upon the importance of absolute freshness, cleanliness, and purity in

the whites, without which a perfect and brilliant picture cannot possibly be hoped for, he devotes himself to the question of tone. He says:—

“The tone, I am well aware, is a mooted question among artists, or ‘so-called’ artists; for he who contends that the brown tone is the proper one does not fully understand his business, and I can prove it. There never can be made a clear flesh and blood face over a brown tone. Especially is it impossible to depict certain varieties of complexion true to life, with their marvellously pure sea-shell tints, and transparent blue traceries of veins. Where the deeper shadows are above the eyes, under the chin, and some other occasional shades, the tone does not matter—it is well enough there; but in the lighter shadows, on the temples, brow, under the eyes, about the mouth, and on the neck and bosom, there should not be a trace of brown; for these are delicate shades, greyish, or inclined to blue or green, and must be pure and transparent, showing no dirty undercurrent of any other colour, and especially any colour made in the photograph.

“The painting which shows the photograph peeping through its colours reminds one of that economical young woman who inquired how much it would cost to have one coat of paint on her picture.

“The photographic print should be used simply for the assistance its outlines give to the production of a correct likeness; that secured, it should be completely covered, painted out, and entirely lost for evermore to mortal vision—only the painting left, with its firm flesh and graceful draperies, standing out independently from the distance of the background.”

Blue tones are little better, he thinks.

“There are certain complexions which cannot be painted any more successfully over a blue tone than can some others over the brown.

The perfection of tone for all kinds and descriptions of to-be-painted pictures is, in his experience, “the clear neutral grey, than which there can be none more suitable. For crayons and inks this is the only one that is admissible, inasmuch as it is impossible to hide the photograph in those truly beautiful productions of art when the prints have any approach to colour, as red, brown, or blue. And these pictures, bear in mind, are expected to delude people into the belief that they resemble fine engravings; and properly made they do, only that they surpass them. But do you not see that these coloured faces, stippled with black, bear not the slightest similitude to an engraving, with its pearly lights and effectively transparent shadows? To cover the brown tone of the shadows, the crayon must be ground in until it reaches a density that gives an effect too sooty for any white citizen. This never will do, so the brown shadows and red half-tones must be allowed to look through the crayon; the lighter parts of the background must remain of this same colour, so decidedly foreign and inimical to the supposed object of the picture, and the high lights in the drapery must also take part in the general discolouration.

“When we attempt the portrayal of flesh in colours, on canvas or paper, all acknowledge that there cannot be too great care in searching out in the human face, and perpetuating in the pictured one, all the delicate tints and all the peculiarity and richness of colour that can be found, to make it approach, as nearly as lies in human power, the living, breathing original.

“Many unquestioningly believe that plain paper is to be subjected to like treatment with albumen; they use the same fixing and toning baths, and the same time in each is allotted to both. This is a serious error; and though I do not know the *modus operandi* by which magnificent results are gained, I do immediately recognize a result, be it magnificent or otherwise. The brand of the paper, as far as I have noticed, makes but little difference. The ordinarily used paper is all good if only it receives proper attention and treatment.

“Sometimes the innocent paper passes through such

processes of torture, that it comes forth roughened and coarse-grained, with a surface like blotting-paper; so extremely like, in some cases, that the most carefully laid-on washes leave a hard line wherever the colour stops its flow, which will be without any warning, and on every possible occasion.

“This rough soft paper can be used to better advantage for large pictures; but there is certain failure in any attempt at the elaborate finish required for small ones.

“Still, a really better effect can be obtained even with such paper than with that so glossily smooth that colour will only partly absorb and barely adhere. That the picture should be a permanently enduring creation, the paper must be capable of absorption to such an extent that its fibres can be completely saturated with colour, so that the well-diluted tints can be soaked in, little by little, till it is full to the surface. Such a picture cannot fade or easily be destroyed; but we cannot say as much for these with hard smooth surfaces, on which thick colour must be stippled with a fine-pointed brush. Such can but be the merest daubs, and liable to perish soon from the face of the earth, which is one comfort.

“Now we come to the treatment of copies. We have to copy, often, old card photographs made, perhaps, in early photographic days; as yellow as gold, and the albumen surface veined with seams and crossed in all directions by minute breaks in the albumen. Enlarged to even the ordinary three-inch head, we have the face divided into sections, like a railroad map, by immense fissures and chasms. This has rather a dubious appearance; but there is no cause for any alarm as to the final issue. Only do not make a print from the negative as it is in its native rugged state, and send it to be finished. There will be no high-lights in a print from such a negative: yellow photographs dark—an assertion which, although not original with me, is nevertheless true, and one of which it is too frequently my painful duty to remind many a first-class photographer. Then where the high-lights should be, in this copy of a time yellowed photograph, will be half-tone, possibly three-quarter tone. This cannot be entirely remedied by the artist. By making the shadows very deep he can always brighten other parts of the face by the contrast, and he can (and too often feels compelled to) resort, in addition to his legitimate means, to that crime against good taste, of using chalk for lighting ink pictures, and mixing colour with white paint for water colours. This is detestable, and the more so when five minutes of careful manipulation of the negative before printing would obviate all such necessity.

“Varnish your negatives with retouching varnish; then, with cotton stump and powdered lead, go over all those portions of the face where high lights should be; pay strict attention as you go to the copied photograph, that you may not produce a light where rightfully belongs a shade, and thus make a change in the likeness, which may cause the artist much trouble and labour to restore. Then, with a soft pencil, work along on these crossing and recrossing lines of shade, caused by the breaks, making them to correspond as nearly as possible with the surrounding portions of the face. Better make them lighter, though, than otherwise, for you will remember that white can be made to receive any shade of colour, either light or dark; but that which is printed dark cannot be made lighter, and at the same time present a respectable appearance, for black is independent and obstinate, and will keep its personality, in some degree, to the last.

“Any artist who lives where he can visit the gallery from whence he receives work will be willing to attend to the negatives himself; but if the work has to be sent any distance to be finished, the retouching of the negatives must be left to the photographer, and in most cases he will be not only willing, but anxious, to receive instruction in anything that will better his work.

“I will now mention the orthodox manner of dealing with copies when changes in the drapery are required to be

made. Before beginning, however, I wish to make an apologetic bow to those who know all about it, and say that I am not instructing them at all, only those who need and desire such information.

"Many of you would be surprised to know how lamentably deficient many otherwise good photographers are in this department. If I had not personally instructed so many, and had seen the sad need of instructing ten times as many more, I should be incredulous too. I suppose the reason is, that many had not until quite lately had much copying to do, and feeling more interest in their so-considered more special province of making albumen photographs, have not devoted the necessary time to the ways and means to be employed.

"We occasionally have pictures to copy of gentlemen with high, closely-buttoned vests, which it is desired should be made open in the painting, displaying the white shirt-bosom, collar, and tie. Now, is it not a severe strain on the credulity to believe that any one in his right mind would have so little thought (to speak very mildly indeed) as to send a print from the negative in its primitive state, expecting a brush and water colours to hide this black mass of broadcloth and buttons with the snowy plaits of a shirt? Yet such prints are sent frequently, and very promptly returned. One would suppose that even a stranger to our ways that are so dark would see that this thing never could be done in a way to disguise the apparent fact that the man was suffering from cold, and wore two vests of different pattern, with a very thin white garment between, for the under-vest certainly could show itself through the bosom of the shirt. A piece of paper, the size and shape of this ungainly garment, then, should be pasted over it in the negative, which will cause in the print a white space, whercon the artist has the opportunity of exercising his skill, and manufacturing the missing garments to his own taste.

"Perhaps the background is spotted, clouded, and scratched: then, by the process known as double-printing, make a smooth, even, light background, on which anything can be accomplished; or if the picture is to be ink, the print may be made with a white ground to be finished in vignette form.

"The process of double-printing is a very necessary and quite simple one. First make a print; then cut, with great caution and a keen knife, the face and figure—or all that is to be a part of the completed work—from the remainder, or that which is to be changed. Fasten this discarded background by the corners to the film side of the negative, and allow the face and figure to print as long as is necessary. Then, as expeditiously, and in as dark a corner as possible, remove both background and negative from the printing-frame, insert instead a perfectly clean square of glass, and the new print, which is now on a white background. Now place the other part of the first print over the figure, that it may not become darker, and allow the background to acquire the desired uniform depth. This method is well known and long practised by photographers, but there are many who are quite innocent of ever having resorted to any such expedient.

"Supposing we have a picture of a gentleman with his hat on, sent, accompanied by a description of the concealed forehead and hair, with the request that the hat should be removed. The course to be pursued in this case is to make a print, and cut out the face and form, leaving on the background the hat, together with the deep shadow that it casts on the forehead. Fasten this to the negative (after touching out any dark foreign spots or scratches which may be on the face), and make your print on a white background. The background must not be printed at all in a case of this kind, on account of the forehead, which is better unprinted. In short, every part of a copied picture which is to be removed at all should be blocked out in the negative, leaving a white space.

"The most of my acquaintances among photographers are

large-hearted, and willing to do almost anything for the sake of conferring a favour, if nothing else; and, in addition, their minds are ever filled with the desire of increasing their knowledge and rising higher in their well-beloved art. I am sure it occasions an artist as much sincere regret to be compelled to return a print, with an expression of dissatisfaction, as it does the photographer to receive it, and to number it among his other trials and vexations of the day. I, for one, do above all things dislike to make such a return. It is desirable that there should be greater unanimity between the photographer and artist, and when such a feeling has become universal the many good results will speak for themselves. On all those who desire and work for such existing harmony between our two brotherhoods, I pronounce a benedictio."

### THE INFLUENCE OF "RETOUCHING" ON PHOTOGRAPHY.

BY WILLIAM HEIGHWAY.\*

LOOKING back a few years at the best specimens then existent of photography, the most casual observer cannot but be struck with the wondrous improvement of late years. This progress is in the artistic, rather than the chemical, manipulation. A look at the negatives of six or seven years back will show that in cleanness and beauty of chemical working they are in no ways behind those of the present day; but what else do they show? Flat, uninteresting lighting, hideous posing, backgrounds flat (or, worse, unmeaning and often impossible painted scenes), and on the human face divine every freckle showing with exaggerated prominence, with an extreme roughness of the skin. In the increased beauty perceptible in the negatives of the present day we see the evidences of many improvements—artistic backgrounds, the lighting of the subject, the shadow effect (labouring under the painful and ridiculous misnomer of "Rembrandt effect"), more tasteful styles of pictures; and last, but not least, the retouching of the negative, to which, in a great measure, is the advancement of late years due. Let me explain that I do not go to all the lengths that the partisan on the side of retouching urges in extenuation of his abuse of this means of beautifying the picture; but I do believe in its right use. It has led us to a higher belief in the power of our art, and with this belief planted in the mind the thoughtful photographer has aimed higher, and is still striving to surpass all that he has yet done, adopting as his motto the ambitious word of conscious power, "Excelsior." By the aid of the pencil the artist is enabled to abolish the black spot which is the chemical rendering of the yellow freckle—almost imperceptible in nature—and this of itself is no mean power; but, beyond this, what scope an artist has in perfecting his picture, by being able to strengthen lights, where necessary, and softening harsh shadows. There are, it is not to be denied, too many who prostitute this power, and so "beautify" that all the nature and individuality of the face are lost, and a marble-like smoothness substituted; but because injudicious and ignorant workers do this outrage on art with the pencil, shall we deny it the meed of praise it deserves, or decri it as a system pernicious and destructive to photography? Rather let us educate ourselves to know how far it may be carried to be a valuable servant, and avoid allowing it to become an exacting master. There are those who, jealous of the power given to the retoucher, affirm that the beauty of the works of great masters in photography is entirely due to the skill of their retouchers; but this is a great mistake, for never yet was a bad negative transformed into a good one by that means. Even were this silly assertion true, it would be rather an argument in its favour—only it exists so: an artistic picture is only to be produced by the photographer who has the artistic knowledge, and knows how to apply it.

## ON THE YELLOWNESS OF NEGATIVES.

BY K. SCHWIER.\*

FOR some time past I have had to contend with a peculiar phenomenon, which appeared upon many of my plates and caused them to print too deeply. The clichés became in part yellow, and in those places, mostly, where the streaks of varnish were visible, whether these were regularly around the margin, or in the middle of the plate, in case the same had been carelessly varnished.

In January of last year, Professor Vogel called attention to the circumstance, at one of the meetings of the Berlin Society; but no one seemed to be able to afford a satisfactory explanation on the subject. Whilst looking through a series of plates to sort the good ones from the bad, I selected a few of the worst specimens with these yellow patches, that print white upon the picture, and endeavoured to restore them in some way. When the yellowness covers the whole of the plate (as is sometimes the case), the result is a very hard print indeed.

After many unsuccessful essays—exposure to alcoholic fumes, softening the varnish with glacial acetic acid, &c.—I at length hit upon a method which is as simple as the result is successful. The negative is first washed over several times with alcohol diluted with one-fourth or one-fifth its volume of water, just in the same way as if a developer were being applied. In this way the coating of varnish is removed. Singularly enough, most of the retouching remains upon the plate, and is only removed by continual washing in water afterwards. As soon as the plate has been sufficiently freed from the varnish, a ten per cent. aqueous solution of cyanide of potassium, with about double its bulk of alcohol, is employed in the same way, until the yellow spots disappear, even if they are located between the collodion and the glass.

After this, the plate is laid in a dish of water to which one-fifth to one-eighth of alcohol has been added, and the glass moved to and fro for a while. It is then taken out, the film washed two or three times with water, until the last washing does not taste of cyanide any more. The restoration of the cliché is now complete, and when dry the plate is again varnished. The action of the cyanide of potassium is not an un-energetic one, but it is called for by the fact that a negative—especially if much printed—always becomes denser by degrees.

I have come to the following conclusion in regard to the formation of this yellowness. The phenomenon appeared, at first, on those negatives which, soon after their production, are printed without ceasing. Much slower and less energetically is the yellow colour in appearing in plates which are rarely printed, and only have an impression taken off now and then; and it is scarcely to be seen at all in such clichés—in portraits, for instance—from which only a couple of dozen of copies are taken. At first I thought the cause was in the dextrine which I employed; but other plates, I found, became yellow quite as soon. Then I fixed the fault upon the soda-paper pads put into the pressure frames; but the defect continued long after their removal. The phenomenon was observable with plates having a substratum as with those without. I now ascribe the defect to the varnish alone. I used to prepare the latter according to Grasshoff's prescription; but lately I have added more shellac, and made it harder. As it was slightly damp, it attracted some portion of the silver from the silver-paper placed in contact with it, and this salt adhering, the cliché gradually darkens the latter. It seems, therefore, almost impossible to prevent the occurrence of the phenomenon, for if one uses a negative varnish which is not tough, and, consequently, somewhat damp, then splitting of the film becomes rife, owing to its brittle character. But I am in hope that a further addition of shellac to Grasshoff's formula will have the effect of preventing this

yellowness from forming, and I find that the coating is still tough enough, under these circumstances, to admit of retouching as before.

## ON THE COLOUR OF NEGATIVE FILMS.

BY F. WALLER.\*

IT is a fact known to almost every operator, that the colour of the negative film has nearly as much to do with its printing qualities as its density; and while this has been noticed and commented upon, both in the foreign and domestic journals, there have been few, if any, theories put forward as to what chemical or other action the colour is due, or why the colour should vary so from time to time under, apparently, the same conditions.

The colour which is conceded to be most desirable is the olive brown, and negatives possessing that creamy appearance produce better prints than those bluish or slate coloured. Now as the colour certainly has so marked an effect, it becomes of vital importance to ascertain what conditions give this colour uniformly, or how this colour can be uniformly produced upon negatives that have it not, without injuring them by forcing them.

Mr. Elbert Anderson (of New York) and I have had some correspondence upon this subject, of which I propose to give the gist to the reader, hoping that while my friend or myself have not arrived at a definite conclusion as to cause or effect, the perusal of this article will stimulate inquiry in this direction, and that other operators will take note of their films, so that by comparison of ideas and results we may arrive at the true cause of coloured films.

Now that all are striving so hard to obtain the softest effects and fullest detail, anything which adds to the printing qualities without interfering with the other essentials is of special interest. Mr. Anderson writes:—"I have tried everything in the developer without effect. Do you think the strength of the developer can effect the film?" After experimenting on both sides, we concluded it was not the developer. I then wrote to Mr. Anderson and suggested that the desired colour might be produced in some way, and mentioned chloride of gold as giving a fine colour; but he soon found out a better plan, and wrote:—"You can get any amount of olive brown on your films by flowing the plate after fixing and washing with a weak solution of cyanide, or by adding enough cyanide to your hypo to fix in half the time." I found it to work admirably, securing good colour films in that way. But neither Mr. Anderson nor myself were quite satisfied, because we have not as yet found the cause of the colour, as it at times appears without any extraneous aid. So we have resumed our experimenting. Having seen it stated that blue films came from cadmium collodion, brown from potassium, we experimented with several kinds, also with the bath in all conditions, strong, weak, acid, and nearly neutral, without marked effect. Different acids were also employed in the developer, but this seemed not to alter the colour.

I was at first inclined to think it lay in the condition of the bath, and that the stronger the coating of iodide of silver, the browner the film. But experiment did not prove this. The time of exposure was then tried; but I found upon short-timed negatives just as good a colour as upon full-timed.

I am rather of the opinion that the newer the fixing bath the browner the film, and when the bath is full of hyposulphate of silver, that affects the colour. But I have not as yet made a thorough trial.

We all have noticed the dull and slaty look a negative has which has been left in the hypo and forgotten; then the hypo had some colouring effect. Perhaps the reason we sometimes have good coloured films, and at others poor, rests with the age of the fixing bath. Let us hear from you, gentlemen of the dark room, and give us your opinion of the matter.

## MECHANICAL GRAIN IN PHOTOGRAPHS.

THE use of a mechanical grain, like that produced by stippling or hatching, which is a necessity in lithography, wood cutting, and copper-plate engraving, as being the only mode by which gradation from light to shadow can be rendered, is not a necessity of painting or photography. The painter in water or oil can secure gradation in continuous flat tint. The pictures produced by photography, although, of course, monochromes, possess gradations from light to dark in one continuous flat tint of that monochrome; and in this respect photography would seem, at first sight, to possess an advantage over engraving and lithographic processes. But whilst a continuous tint possesses an advantage on the score of delicacy, it possesses in many cases a certain want of transparency. The painter in oil secures the effect of transparency by glazing a transparent colour over his solid painting, as by working in tints in a manner resembling stippling before the former painting is dry. The miniature painter using water colours, having washed in his tints, proceeds to get modelling, transparency, and richness by stippling. Everyone must have been struck with the inferiority of effect in a photograph, as a rule, when hung, as compared with that of a fine engraving. Examined in the hand, all this advantage might rest with the photograph; but the moment the two are placed at a distance from the wall, the photograph looks heavy and lacking in light and transparency. The peculiar gradation of the engraving, whether in line, stipple, or hatching, has the quality of letting light into the applied tints, which at once removes the effect of opacity and heaviness.

Many photographers have had a craving for some similar effect in photographs, and various modes of securing it have been proposed: printing through ground glass, printing on rough drawing paper, stippling the print in black and white, and other methods. A year or two ago Mr. Faulkner called upon us to ask for information as to the various experiments which had already been made in that direction, informing us that he had just taken preliminary steps for securing a patent for a method he was working out. Unfortunately for Mr. Faulkner, and probably for the public, the method, although less known than it ought to be, and probably nowhere in practice, was not new, and the patent could not be completed. We say probably unfortunately for the public, advisedly; for whilst a strong antipathy to patents is entertained by photographers generally, who have been accustomed, except in rarely exceptional cases, to receive freely, and at once apply unrestrictedly to their own uses, all discoveries in their art,

we are satisfied that in many cases they are absolute gainers by the practice of improvements being patented, provided that the patented method is made accessible upon liberal terms. They are gainers in this way: when one person has a special beneficial interest in an invention, he spends much time, money, thought, skill, and ingenuity in improving his invention to the utmost, and in making it known as widely as possible, because the more he improves it, and the more widely he announces it, the greater are his gains. If no protection exists, no one has any special interest in working out all the possibilities of an invention for the public benefit only, and no one has an interest in calling special attention to the advantages of the invention.

To return, however, to the subject of grain in photographs. The method of introducing grain which Mr. Faulkner proposed, and of which he showed us some charming examples, consisted in introducing a grained transparent screen between the paper and the negative in printing. Our somewhat disappointing answer to his questions as to the novelty of the results consisted in producing an example which we had ourselves produced some years before, when working out experiments in a similar direction. "Why is a method like this not well known, then?" was the natural query; to which our answer was the production of a back volume of the PHOTOGRAPHIC NEWS containing the details. Unfortunately many such things are published, but, for lack of persistent iteration on the part of some interested, and lack of display of examples, such things often gain little attention, and are often forgotten. We had used as a screen a thin sheet of gelatine, upon which had been printed an exceedingly fine aqua-tint grain, the screen having been originally prepared for experiments in securing photo-engraving plates and photo-lithographic stones with a similar grain, as a means to obtaining half tone. The result of printing with this fine aqua-tint grain was in many subjects very pleasing, giving a general softness and transparency to the print generally. Mr. Faulkner's project was to work out the special advantages of various kinds of grain for various subjects, his exquisitely fine artistic taste and his experience in connection with art giving him especial fitness for working out the subject to its most satisfactory issues. Whether he has given the subject further attention we do not know; but we believe it is well worthy of a much fuller and more experimental consideration than it has yet received; and reprinting here the provisional specification, we commend the matter to those of our readers interested in methods of giving to photographs varied art qualities. The specification is as follows:—

"The object of my invention is to improve the effect of photographs produced by light printing from negatives by giving them a lined, dotted, stippled, or any similarly varied ground. For this purpose, according to one method of proceeding, I draw, paint, or photograph on paper, canvas, or other surface, a groundwork such as will give the desired effect on the picture; this may be done in lines, dots, or washes of any design. From this design a negative is prepared on glass, paper, or other surface by any known photographic process. When this negative is produced on glass it is transferred to any thin substance, such as paper, gelatine, collodion, or talc, which may be done in the following manner:—I pour over the negative a solution of gum, gelatine, india-rubber, or any substance suitable for producing a film which protects the negative. When this solution is dry, a tough special collodion, ordinarily called 'transfer collodion,' is poured over it, and when this is thoroughly dry the whole is soaked in water. A strong leathery but transparent film, consisting of the original collodion negative, the protecting substance, and the transfer collodion, can then be removed from the glass to be used as hereafter described. As this mode of producing such a film has been used for other processes I do not consider it part of my present invention, but describe it only in order that my process may be understood. This film containing the negative of the groundwork is interposed between the negative of the picture and the surface on which it is to be printed by light. If the negative of the picture is on collodion film, paper, talc, gelatine, or any such substance, then the groundwork film produced as above described can be used either in

front or at the back of the principal negative, according to the effect desired to be produced. When it is desired that the picture should present the effect of a line engraving, the groundwork negative may be produced from wire gauze or fabric of suitable pattern. Should it be desired that one part of the picture should show the lines more strongly than another, a part of the object may be shaded or thrown a little out of focus by inclining it more or less to the plane of the picture, or a lens may be employed which focuses part, but not the whole, of the object. By these or similar means, a great variety of effects can be produced on the groundwork. Also the negative of the groundwork can be made of various thicknesses, so as to produce a softening effect in printing.

"The gauze or fabric employed may be of very fine mesh when minute lining is required, or may be of large mesh or magnified when bold lines are desired. Also two or more thicknesses of gauze may be photographed, in which case one, being well focussed, would give definite lines; while the others, being out of focus, would give a shaded effect.

"Instead of wire gauze, natural objects may be employed, in some cases with the aid of the microscope; as, for instance, animal or vegetable tissues, wings or eyes of insects, or such like objects. A dotted effect can also be produced from a pigment held in mechanical suspension in liquid which may either be contained in a glass trough, or spread as a film on glass, so that a negative may be taken from it, which, applied as above described, will give the effect of a stippled engraving. By combining such a negative with that taken from gauze, a combination of the stippled and lined effect will be produced. And thus it will be readily understood that a great variety of effects, such as those of a line engraving, aquatint, mezzotint, or stippled drawing, or a combination of any of these, may be attained by these means, and that these are applicable to ordinary photographs or to enlargements, or to the various preparations ordinarily employed for printing mechanically or otherwise from photographs. The groundwork films produced as above described may be employed in the printing of many successive pictures. When desirable, such a film can be permanently mounted on the negative of a picture, so as to be always printed along with it, and form part of it.

"It may be readily understood that negative films might be used as I have described, not only for producing backgrounds, but also for showing objects superposed with more or less faintness over the objects of the principal picture, and such superposed objects or films containing them may be used in combination with the groundwork."

### YELLOW SPOTS IN PAPER PRINTS.

THE attention recently called by a lady photographer in France to the formation of yellow spots upon prints, and also by M. de Constant in Lausanne, has led Dr. Schnauss of Jena to investigate the matter. It was believed that the defects were due to the use of tobacco in the studios, and the lady in question stated that since smoking had been prohibited in her studio, these spots had ceased to make their appearance. Dr. Schnauss, however, in the *Photographische Archiv*, is of opinion that the defects are due to quite another cause. In his report he says:—"My investigations led me most rapidly to a positive result. As soon as the spots in question were moistened with hydrochloric and nitric acids they immediately disappeared. I hereupon added a drop of a solution of ferrocyanide of potassium, and obtained an intense colouring of Prussian blue, which was most dark around the centre of the spot. Indisputably, therefore, the yellow spots are due to a compound of iron, probably  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , or a basic sulphate of iron, insoluble in water.

"It is a question where this iron came from. Probably, I should think, it is due to the circumstance that in the photographic laboratory there is always a large quantity of sulphate of iron, or the double sulphide of iron and ammonium, lying about, in the scales, on the tables, &c., and dust or solution has touched the paper. Exposed to the air, sulphate of iron becomes a loose and very powdery compound, which could easily be blown about by a puff of wind, and it would be exceedingly injurious if the pictures were in a wet or damp condition.

"Quite the same phenomenon, but in a more visible

shape, photographers find upon the cuffs and sleeves of their shirts, the well-known iron-mould markings, which are generally to be removed by the application of dilute hydrochloric acid."

### PHOTO-LITHOGRAPHY AND PHOTO-ENGRAVING WITH BITUMEN OF JUDEA.

At the last meeting of the French Photographic Society, M. G. Fortier exhibited to the members a zinc plate upon which a photographic image had been placed, and another plate engraved for typographic purposes, likewise produced from a photograph. He employed bitumen of Judea in the production of these printing blocks, using this material in preference to bichromated gelatine. His remarks upon the subject were as follows:—

"Whatever care is employed in the production of photographic impression by means of gelatine, whatsoever process, I have found that it is impossible to secure delicacy equal to that furnished by bitumen of Judea dissolved in benzole. It is necessary that the film produced should be a thin one, for unless this is the case, it is a most difficult matter to obtain fine lines in the engraving. As a matter of course, a very good negative is always required—one with clear whites and blacks. Intensifying by means of sulphide of potassium is always disposed to cake up the blacks, and to render the lines a little ragged. The best results are obtained with a very clear and tolerably transparent cliché, and not with an opaque negative that has been intensified.

"The bitumen of Judea takes the ink very readily, and resists the action of the acid when you proceed to etch the plate. As far as my experience goes, it is best adapted for the reproduction of all line drawings and engravings."

M. Gobert confirmed M. Fortier in the matter, and said he preferred, also, to use bitumen of Judea. He coated his plate with a very thin film of solution, and, after drying, he exposed and developed with essence of turpentine, the plate being plunged into water as soon as the image comes out clearly; or water might be poured over the plate obliquely, which had the effect of sweeping away the turpentine very completely. In winter time he advocated warming the essence of turpentine a little. The bitumen image, inked immediately after development, absorbs the ink well, and forms a capital basis for printing.

### THE PRACTICAL PRINTER IN AMERICA.

#### II.

IN the comparatively limited amount of photographic literature which has been devoted to silver printing, considerable difference of opinion has prevailed amongst theoretical men as to the best strength of the nitrate bath, the time of floating the paper, the constitution of the bath, and the relative effect of variations in these respects. Amongst practical men probably not much difference of opinion has prevailed, but they, with bright exceptions, unfortunately, but rarely join in the discussion of questions in which their dicta is of the utmost value. A dozen years or more ago, a bath of sixty grains of nitrate of silver to the ounce constituted a common but minimum strength; and variations from that standard up to one hundred grains per ounce were not uncommon, the higher strength being generally recommended as a means of securing vigorous prints. In the energetic discussion on the subject some years ago we took a prominent part in recommending the use of weaker solutions of silver, and of the lighter salting of paper, which should, of course, be a necessary preliminary to the use of the weak silver bath. At one time an albumenizing bath with twenty grains of chloride—commonly the chloride of ammonium—to the ounce was not uncommon; now, probably, not more than from six grains to eight grains to the ounce are generally used, whilst the

average strength of the silver bath in most frequent use is probably about forty grains. Mr. Hearn speaks of thirty grains in summer and forty-eight in winter with a paper he often uses.

To the influence of the time of floating still less attention has been given; but our American practical man deals minutely with it. He observes:—

"It might be supposed that a weak silver bath would necessitate a longer time for floating than a strong bath would, and also that a bath weak in the number of grains of silver to the ounce of water would be more economical. Now this is a mistake. When a sheet of salted albumen paper is floated upon a bath of nitrate of silver, the salt in the albumen will take up the silver which it needs, whether the bath is a strong or a weak one, and chloride of silver will be formed. The albumen will also take up some in the form of albuminate of silver (Vogel's Handbook); and then, if the sheet is allowed to remain on the bath too long a time, there will be more of the solution absorbed than what is really necessary, which will penetrate through the surface and far into the albumen. The paper thus floated and printed will have a sunk-in appearance, owing to the silver discolouring, which is absorbed far into the albumen, as before said, during the lengthened time of sensitizing.

"This sunk-in appearance is not the only fault with long floating on a weak bath; but the albumen will be dissolved off, being left in the bath, and the paper will not print brilliant, but dull; and often flat prints will be the result."

In the next paragraphs Mr. Hearn is somewhat at variance with most authorities; but he is, we think, with certain qualifications, right. An old rule was to float on a strong bath a very short time; but the practice not unfrequently led to irregular and unsatisfactory results, uneven patchy prints being commonly produced. Nevertheless we think the rules which follow are somewhat too absolutely stated, really long floating on a strong bath being, in our experience, a mistake. Mr. Hearn says:—

"A strong bath necessitates a long time of floating, because the albumen on the paper is at first coagulated by the strong silver solution, and it takes quite a number of seconds for the albumen to commence to take up what silver it needs, whereas the albumen on the paper not being coagulated by the silver in a weak bath, it will more readily absorb that silver which is necessary for the production of a good print.

"From this we find:—

"1st. That a strong silver bath requires a long time of floating.

"2nd. That a weak silver bath requires a short time of floating.

"3rd. That a medium silver bath requires a medium time of floating.

"There are, however, bad results obtainable by floating the paper a long time on a strong bath, as well as floating a short time on a weak bath.

"When we float it a long time on a strong bath it will, when printed, make a bold and brilliant print, but the shadows will be very much bronzed, even when the prints are mounted. When we float the paper a short time on a weak bath, it will not be at all bronzed, but the prints are likely to be weak; and, on the other hand, if we float the paper a long time on this kind of bath, the silver will be, as has been said, sunk-in, or, as it is sometimes expressed, the paper will be 'wooly.'"

That the shadows will be much bronzed with a paper floated long on a strong bath there cannot be a doubt; but the details in the shadows will be buried and lost, and the result will be a heavy, not a brilliant print. Of course the negative will largely determine the result; but we are here speaking of the use of an average good negative of proper intensity. Mr. Blanchard pointed out some years ago that with a somewhat weak negative, full of detail,

but lacking in contrast, the use of a strong bath was ruinous, the detail being buried in one flat, dull, even mass; whilst with a weak bath, clear, brilliant prints could be obtained with such a negative. Mr. Hearn is conscious of the danger of taking his rules too absolutely. He says:—

"I do not mean by the first two remarks made above that the extremes are to be indulged in, for then, in a measure, arise the bad results named, and in the case of the weak bath the abuse of the remark will be more especially a source of failure.

"We cannot, to obtain good results, use a bath weaker than thirty-five grains, or stronger than sixty grains of silver to the ounce of water, with many of the brands of paper which are generally used, while with other brands, thirty grains in summer and sixty to seventy in winter are best.

"For the excellent brand of paper known as the 'Berlin,' I found, with the class of negatives I printed when using that paper, that a medium strong bath (say of forty grains in summer and fifty-five to sixty grains in winter) of nitrate of silver to the ounce of water was best, while with the 'Hovey' brand of paper, a bath of not more than thirty-three, or less than twenty-eight grains of silver to the ounce of water, with twenty-five seconds' floating, was necessary during the summer time; and in the winter, when the negatives are printed on the roof, I have known of a bath of seventy grains of silver alone, and from two to three minutes' floating, to be required to obtain good prints from the very thin negatives that were made.

"A weak bath loses so much after silvering a dozen sheets or so, that it commences to make itself felt, and consequently needs strengthening about all of the time.

"A strong bath loses also, but the silver is not taken up in so large a proportion as it is in the weak bath, and the strong bath can be used for a much longer time, even until there will not be enough solution to sensitize the paper, without giving the printer any trouble whatever.

"The prints will be better in many respects with an average bath than with either of the extremes, as a trial will show to the observant printer.

"All of the solution that is on the paper should be, as much as possible, on the surface of the albumen, to prevent 'wooliness,' and so as to have bold, vigorous prints, which can be easily freed from the nitrate of silver in the washing."

## SQUARE CAMERAS AND SQUARE GLASSES.

BY J. H. B.

SURELY the time has now arrived when the old form of plates and cameras should be abolished, and both should be made square. When the finished picture was produced in the camera, as in the Daguerreotype and glass positive processes, there was some reason for the sensitive plates being of an oblong form; but now no such necessity exists, and it would be far more convenient in practice if the glasses were square. There would be more margin left for stains and flaws; the collodion and other solutions would act more equally over the entire surface; and, above all, whatever the form of the picture intended, it would be unnecessary to alter the position of the plate in the camera, as on a square plate subjects in which the longest sides are vertical or horizontal can be taken with equal facility, the paper positives being ultimately made of the required shape. It is absurd to say a lens covers 10 by 8, 6 by 5, and so on. If it covers 10 or 6 one way, it does the same the other, and a more correct way of describing its powers would be by giving the diameter of the disc it will cover.

ALBUMEN CHLORO-BROMIDE PROCESS.

BY M. CAREY LEA.\*

It has been objected to the various forms of the emulsion process, that it is inconvenient to be obliged to use the emulsion within a certain limit of hours after it is mixed. If kept beyond that time, inferior results are obtained.

It occurred to me that the new process which I have lately described, and sent a brief sketch of to the last meeting of the Photographic Society—that in which the plate is plunged direct into a bath of albumen, and other agents, as soon as set—differed so much in its characteristics from the older processes, that possibly this difficulty as to the keeping of the emulsion might not exist. So far I have been able to make but a single experiment in this direction, but the result was very curious and satisfactory.

Having on one occasion a small quantity of emulsion over, after coating a batch of plates, I set it aside, and subsequently coated a plate with it. Nineteen days had elapsed between the mixing of the emulsion and the coating of this plate with it. It lay aside for about two weeks, and was then exposed and developed. I enclose a print from this negative. The print does not do justice to the negative, which requires deeper printing, but at this moment I have not a really good print at hand. It will serve to show, however, that the negative is an excellent one.

Of course a principle cannot be established upon a single trial. That the first (and only) trial made should be a complete success, certainly argues very favourably, and it seems highly probable that in the case of my new process, the emulsion without any special preparation can be kept for a considerable time without prejudice to the result.

The emulsion was made as follows:—

Cadmium bromide (dry)...	...	6½ grs. to oz.
Ammonium bromide ...	...	1½ " "
Cobalt chloride ...	...	1 " "
Potassium nitrite ...	...	1 " "
Aqua regia ...	...	2 drops to oz.

Sensitized with silver nitrate, twenty-five grains to the ounce. Preservative bath, gallic acid with tannin and albumen as already described. This plate was as sensitive as those made with freshly prepared emulsion. It was tested against one, and found to be in no respect inferior.

BATHS, ETC.

BY W. H. POTTER.†

HAVING cut loose from portrait photography, and launched into landscape photography, I commenced my operations this season in a campaign against the two Virginias. Of course I have done considerable out-door work, which led me to take this step; but heretofore it has been for recreation and personal pleasure, with a fair portrait business to back me. Now it will be, to a certain degree, a question of bread and butter, combined with the charms of nature—not a very happy combination, but certain to exist in some form.

As to my baths, I make three large ones: two iodized almost up to that point where it ceases to be a virtue, and the other left plain; but all as pure as ice-water, sunning, decanting, and filtering can make them. The bath-tub is filled about two-thirds full. Whenever the bath gives signs of the presence of too much iodide, give it a small dose of the plain bath, not too much. The bath works best very near the turning-point or excess of iodide. The plain solution also decreases the quantity of alcohol and ether to the amount of solution. You can keep on adding, from time to time, plain solution till you get your tub full, and it saves a great deal of time when Dame Nature is

balmy, sunny, beautiful, and calmly submits to that tide of success which, "taken at the flood," brings forth such negatives that make your heart throb for more room. Also, the plain solution is ready for re-developing solutions for instantaneous negatives, &c.

Never take the iodide out of your bath. It is only a waste of silver, profitable to no one but the refiner. As long as you keep or bring your bath up to the original quantity and strength, you will not have pinholes from too much iodide. Prove it by purifying or freeing your bath of alcohol, ether, and dirt, and by adding silver and water, and bring it up to the original quantity. If eighty-ounce solution at forty grains is reduced by dirty plates to sixty-ounce solution, you may expect pinholes. Reduce your vital force from eighty degrees to sixty by letting off your blood, and I presume you would feel funny too. You eat three meals a day, and you should at least give your bath a supper.

Another tight-top bath is used to clear up negatives. Solar negatives should be fixed immediately to secure all the delicacy possible. By fixing and varnishing good negatives on the spot, you shall not have cause to regret afterwards that you possess so much common sense. Those gentlemen who rush through the country making fifteen or twenty negatives a day, must retire sooner or later before the men who make three or four faultless ones. The demand now is not quantity but quality. Landscape photography is behindhand in prices, and something more, is in the mud. But there is a place of honour and profit for it, as well as the one already reached by portrait photography.

Another tub is filled with acid. After you have selected two of the best, not passable, negatives of any one subject, rub off the film of the rest, put them in the acid a moment and wash them, and, if time is not precious, albumenize. By keeping your plates out of the dirt, cleaning off, and using the acid, &c., they are always ready to be used over and over without risk, and in the long run you save time; for what is more mortifying, when the light, &c., is just right, than to find that you have exposed a dirty plate?

Make at least two good negatives of the same subject. If it is not worth two negatives, don't make one, as there is no fortune or fame in it. Aim high: you will come far enough short then; and if so, where will the indifferent or "Tinkering Jim" appear? The crown is for that man who patiently toils till he reaches the top of the ladder. What is the comet or meteor compared with the constancy of the sun? Resolve, if God gives you life and health, that you will reach the high prize you have fixed your eyes upon. Do not take into consideration failure and disappointment; they are only your drillmasters. They are only mistakes to be rectified by experience.

In my next, the four kinds of collodion used in my operations, the developer, and what I saw on the Kanawha, &c., will receive attention.

Correspondence.

PORTABLE SCREENS IN PORTRAITURE.

DEAR SIR,—We have been pleased to see to-day your leader in the PHOTOGRAPHIC NEWS on "the use of portable screens in portraiture," as it is a subject to which we think sufficient attention has not been paid by the bulk of the profession in this country, which is the more astonishing when we see what beautiful effects in lighting are obtainable by their use. But to show you that some of our leading photographers are not behind their American brethren in these matters, we may add that we have supplied several of these very useful appliances during the last fifteen months, and we are indebted to Mr. Vandyke, of the eminent firm of Vandyke and Brown, Liverpool, for the first suggestion. We made the first screen for that firm,

\* Read at the June meeting of the Photographic Society of Philadelphia.  
† Philadelphia Photographer.

and we have had the pleasure of seeing its exquisite results in the productions from their studio, where it is in constant use. The form of our screen differs slightly from that described by you, in its being *circular* instead of oblong. Mr. Vandyke (whose opinion we value as of the highest) assured us that the *circular* is the best and proper form of making such screens.

We first make a wooden framework, upon which we stretch canvas on both sides; one side we paint a dead white, the other a dark salmon colour; we make it easily and quickly reversible by means of a horizontal bar fitted with slot and screw, and at the centre, attached by a short wooden arm to a ball and socket joint, held fast in any position by means of a set screw. Thus the screen can be placed at any given angle in a moment, and firmly fitted there. The wooden arm is extended the necessary length beyond the ball and socket, and fixed to an iron rod, which is fitted into an ordinary headrest stand with set screw, so that the whole can be raised or lowered to any required position.

It is very simple and cheap in construction, and handy in use. It is invaluable for a studio lighted only on one side, or where a large amount of top light is introduced, for by using the white side of reflector the heavy downward shadows are completely under control, and rendered soft and transparent. When (in accordance with your remarks) a shirt front, or other folds in linen, or in a white dress, are to be portrayed, it is the simplest matter in the world to give them their full effect by using the dark-painted side of the screen, which effectually subdues the glare of light reflected from such objects, and, instead of a white chalky patch upon the figure, we produce a beautiful semi-transparent effect, giving the minutest detail in every fold of the costume.

We enclose you a photograph (such as it is) showing a back view of our reflecting screen, and if you think it worthy of further reference or description in the News, we shall be happy to place it at your disposal. And with the assurance of our esteem and regard, we are, dear sir, very faithfully yours,

D. H. CUSSONS AND Co.

54, Houghton Street, Southport.

[We shall have pleasure in publishing a detailed description of the screen in question.—Ed.]

#### IMPROVING THE STATUS OF PHOTOGRAPHY-- A PHOTOGRAPHIC UNION.

DEAR SIR,—It was with much pleasure I read and studied, in the PHOTOGRAPHIC NEWS of 10th June, the suggestions put forward by Mr. Hooper for generally raising the status of our art throughout the United Kingdom. I have long felt that a want of united action and interest has prevailed, and I feel confident that were it possible to draw together the entire strength of the various societies to an agreed centre, and organize the whole something after the manner of the British Association, that a great point would be gained. Although London will always be the chief city, yet there will be increased interest in the art, both by the public and the profession, should it be arranged to hold, periodically, an exhibition and conference in different towns, after the fashion so popular and successful in the United States.

I feel, sir, photographers have themselves to blame for being held in an inferior position by the general public. It is well known that, in the present day, people are estimated a good deal according to the estimate they have of themselves; and photographers, as a class, in this country, are far too modest and retiring. Let them blow their own trumpet a little, and plenty will gather round their standard. Why is it the English public so universally speak more favourably of Continental photographs than of anything produced by their own countrymen? Is not the fault somewhat our own? The light is generally accused with the deficiency; but why admit the fact as a fact? I

always make a point of contradicting such a statement, by telling such connoisseurs that this country stands second to none in the art, and has carried off more prizes than any other, both for invention and perfection of work. I trust I am correct in such statements; but if I err, I would rather err in favour of my own country.

I am not, as yet, a member of the Photographic Society of Great Britain; but should such a scheme as suggested by Mr. Hooper be carried into effect, I should be proud of becoming a member, and trust you, Mr. Editor, as a vice-president of this society, will do your utmost to further this desirable scheme. There certainly should be but one representative journal, and not, as now, two conflicting interests. Why should not any member of any society have sent him, free, a journal containing all the papers and doings of all the societies in the United Kingdom? This, alone, would be a great desideratum.

However, I must not trespass on your valuable space, except to thank Mr. Hooper for boldly putting forth this scheme, and trust it may have the serious consideration of the executive of all the societies of the United Kingdom, and be acted upon without delay.—Yours truly, MINIMUS.

*Fine Art Studio, Cheltenham.*

#### BEER FOR DRY PLATES.

SIR,—In reference to your correspondent's query respecting the best kind of beer to use for the dry process, I can recommend with confidence the ale known as Disher's two guinea ale; it is very rich in saccharine matter, and free from acidity. I have used it both for negatives and transparencies with great success. If the plates are to be used within a few days, the final washing may be dispensed with; and they are then very sensitive, the exposure for portraits with a 6-inch focus lens, 2½ diameter (full aperture), being fifteen seconds in the open air on a bright summer's day. With alkaline developer (which I have never tried) doubtless good results could be obtained with much shorter exposure.

With regard to my plates generally, I believe there is one circumstance affecting their sensitiveness that is frequently lost sight of, viz., the hygrometric condition of the plate at the moment of exposure; of course this circumstance is not under the control of the photographer, but it may serve to explain some of the discrepancies observed in working the same process under apparently equal conditions.—I am, sir, your obedient servant, G. RAMSAY.

#### THE NEW SYSTEM OF COMBINATION PRINTING.

DEAR SIR,—In answer to Mr. Gregson's letter in the NEWS, I must say that his plan is far from my own invention of photo-combination, as he goes back to the registration marks, and my system does not require any; and there is too much time and trouble about his for it to be equal to my own, without saying a word in comparison of results produced by his and mine, as photographers will be able to see the simplicity of it when my specification is published.—Yours respectfully, W. TILLEY.

#### Proceedings of Societies.

##### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE annual trade holiday and excursion, under the auspices of this society, occurred on Thursday last, the 30th ult., when nearly every photographic establishment in the city was closed. The excursion on this occasion was arranged for Amisfield Park, near Haddington, to which place the party, about eighty in number, proceeded per rail, starting at 9.50, and arriving a little before eleven o'clock.

Amisfield Park, the property of Lord Elcho, lies about a mile east of Haddington, and is probably one of the most delightful places for picnic purposes within a radius of fifty miles of the city, consisting, as it does, of a practically unlimited extent of

level, fresh, velvety turf, intersected by the Tyne, and beautifully shaded by fine old trees, the interlacing branches of which screened off the hot sun, and formed, in many glorious places, cathedral-like spaces illuminated by the "dim religious light" so refreshing as havens of refuge from the scorching heat of a July day.

Through the kindness of Mr. Ramsay, the tenant at present in possession of the estate, the well-preserved waters of the Tyne were thrown open to those of the party whose tastes lay in the direction of the rod and line, and very shortly after their arrival, several artificial flies were skimming over the surface of the stream; but, so far as we could learn, the trout declined to rise.

The landlord of the "George" Hotel, who was purveyor for the occasion, had spread the tables under a few of the largest trees, and at twelve o'clock the luncheon signal was given, when, by way of fortifying themselves for the labour of the day, full justice was done to what he had provided. After luncheon the assembly was photographed by Mr. Campbell, and then it broke up into parties of twos and larger numbers, and enjoyed a stroll through the grounds, until the strains of welcome music brought back most of the younger, and some of those who were young only in spirit, to the enjoyment of the dance, which was kept up with unflinching zeal till dinner time. For those who did not care for dancing, several games had been provided, and so all went merry as a marriage-bell till dinner was announced, when what might be called the heavy business of the day commenced.

Mr. THOMAS KNOX, J.P., who, along with his lady, had honoured the company by his presence, was, in the unavoidable absence of the president, enthusiastically called to the chair; and Mr. Colin Sinclair, the honorary secretary, acted as croupier. The dinner arrangements, which reflected much credit on Mr. Stevenson, the purveyor, were eminently satisfactory, and so thoroughly successful; and as soon as the rattle of knives and forks had somewhat subsided, the chairman rose, and said that he knew they were all anxious to be again up and doing, and therefore he would not detain them with long speeches. There were, however, three toasts which they could not leave the table without honouring. The first, as loyal subjects of the best and most loved of queens, was of course the Queen herself, which he knew would be responded to right loyally. After the toast was duly honoured, the National Anthem was sung in a way which can only be attained under similar circumstances. The next toast, he said, was of course the toast of the day—"Prosperity to the Edinburgh Photographic Society." Although he had now been for a number of years a member of the society, his numerous engagements, both public and private, had hitherto prevented his joining the members in their annual excursion; but on this occasion, when he received the billet, he found that he was free for the day, and at once resolved to come, and he was heartily glad that he had done so. The sight before him was one not easily to be forgotten. He did not envy the man who could look unmoved on such a large number of happy faces—faces made happy by the innocent enjoyment of healthful exercise and happy association under heaven's glorious canopy, and amidst Nature's most beautiful works. To him such a scene was a noble teacher, exalting the conceptions and purifying the heart, bringing home more and more into loving harmony with human nature, and so into closer communion with its great Author. He thought the committee had counselled wisely in recommending Haddington as the locality of the excursion. This Haddington was really classic ground, in the highest sense of the term—in the sense that it had produced many men who had made their mark in the world, and of whom any country might well be proud. He would not detain them by going over a list of those men, but he could not sit down without mentioning one, the greatest of living Scotchmen, Thomas Carlyle, the "Chelsea Prophet," perhaps the noblest thinker and most powerful writer of this or any other age. It is yet fresh in our minds that while he was with us in Scotland, getting all the honours that it was possible for us to bestow, the hand of death was, in the mysterious dispensations of Providence, permitted to strike down her who had been long his stay and helpmate, and cast a shadow on his noble life never to be altogether removed. "Those of you," he continued, "who, on your way to the Park, made a passing visit to the Cathedral, as you stood beside the grave of that loved one, and read the simple but touching inscription which tells almost a life's history in a few words, must have felt it difficult to restrain the tears, which, under such circumstances, come unbidden, but hardly unwelcome, to the eyes of all whose hearts are in sympathetic union with their fellowmen. Those present who are not members of the Photographic Society owe a deep debt of gratitude to that body for the opportunity, thus afforded, of enjoying at least one glorious day in the year; and on

the other hand, we who are members feel hardly less indebted to the many friends, especially the many fair friends, who have so welcomingly joined us, and given that nameless something to the trip which goes so far to ensure success. Let us, then, unite our voices in three ringing cheers of well-wishing for continued prosperity to the Edinburgh Photographic Society."

When the enthusiasm had somewhat subsided, at the request of the company the chairman sang "Scotland yet," and then said that there was just one other toast that they must not forget—the health of their two secretaries, Mr. Colin Sinclair and Dr. John Nicol. Who they were, and what they had done for the society, were (amongst the members, at least) household words, and therefore he did not need to say anything in commendation. The success of societies generally, and the success of excursions especially, depended almost entirely on the secretaries, and the success of to-day, as well as all our previous successes, tell, in unmistakable language, that they are the right men in the right places.

When the toast had been duly honoured, Dr. Nicol said, in reply, that although the offices of secretary and corresponding secretary were by no means sinecures, the salaries attached were more than sufficient reward. To have a hand, and a tolerably large hand too, in the management of a society of nearly three hundred members, which had for nearly fifteen years done its fair share of good work, and in which, from first to last, there had never been a jarring word, or even trifling misunderstanding, between any of its members, was, he humbly thought, something to be proud of; and when he looked down the tables at the happy party in the fullest enjoyment of their annual holiday, he was sure he could speak for Mr. Sinclair, as well as for himself, when he said that such a sight would amply reward them for any labour that they could possibly undertake.

Mr. SMALL then proposed the toast of "The Ladies," which was humorously responded to by Mr. DOBIE, and the party then returned to enjoy the dance or game, as suited their fancy.

Shortly before seven o'clock, the signal for assembling was given, and the glee party of Messrs. Ross and Pringle's establishment, of whose merits we have frequently had occasion to speak, favoured the company with some really fine concerted and solo pieces, after which three cheers were given to Mr. Ramsay, through whose liberality access to the grounds had been obtained, and the homeward march was commenced. The party left Haddington at 7.30, and arrived in Edinburgh an hour thereafter, highly delighted with the day's proceedings.

## Talk in the Studio.

ANOTHER METHOD OF SAVING SILVER WASTE.—The peculiarity of this plan is, it saves all the silver. Procure a water-tight tray, with cover, say three feet by five or six, and about six inches deep. Fill it nearly full with sawdust; place it on the roof, or where the sun can shine upon it in the open air; let the washings be thrown upon the sawdust, and assist the evaporation by occasionally turning or moving about with a stick. The sawdust can at any time be burned, and all the silver recovered. The larger the surface, the more readily evaporation is effected.—*Philadelphia Photographer.*

IMPERMEABLE PAPER AND CARDBOARD.—According to Dingler's *Polytechnisches Journal*, if a sheet of paper be immersed in an ammoniacal solution of copper (liqueur de schweitzer), prepared by treating copper filings with ammonia of 0.880 density, in contact with air, the paper becomes entirely impervious to water, and maintains its consistency even under the influence of boiling water. When two sheets of paper thus prepared are passed together through rollers, they adhere completely to each other; and by placing a number of such sheets together, board of great solidity is obtained, which may be still further strengthened by the interposition of fibres or tissues between the sheets. Boards thus formed are quite equal to wood in solidity.

ARTISTIC PHOTOGRAPHY.—Mr. C. D. Mosher, in the *Philadelphia Photographer*, asks:—"Why should we not excel?" and proceeds: "Science and art in photography have attained to that high appreciation of real merit and truthfulness of the likeness that places photography to-day as one of the fine arts, which has been brought about by years of hard study. The old style of photograph had no real art merit in it. The photographer just plumped his patron down in his chair in a full blaze of light, many times as stiff and ungainly as the marble statuary

before the artist hand had given it life; and so it was with photography. Science and art have perfected it, more complete more truthful, than any artist hand can draw by art rules in painting and drawing. The artistic photographer has light and shade, roundness, the true symmetry of artistic proportions, grace, ease, and natural pose, and life-like expression that is not excelled. To-day the artistic photographer can give his patrons likenesses from life, and the beautiful landscape in every form, true to nature, almost perfection itself, with not as much as one hair added to or taken from."

**EBONY FROM SEA-WEED.**—An American periodical gives a process for making artificial ebony from sea-weed. It consists in first treating the plants for two hours with dilute sulphuric acid, then drying and grinding them up. To sixty parts of this product, five parts of liquid glue, five parts of gutta-percha, and two and a-half parts of india-rubber are to be added, the latter two being first dissolved in naphtha. Afterwards ten parts of coal tar, five parts of pulverised sulphur, and five parts of pulverised resin are added, and the whole heated to about 300° Fah. When cooled, a mass is obtained which, in colour, hardness, and capacity for receiving a polish, resembles ebony, and is much cheaper. A process for obtaining a product of this sort from sea-weed was patented some years ago in this country by Mr. T. G. Ghislin, but there was never much commercial result therefrom.

**A CAPITAL ADHESIVE LIQUID**, for sticking tickets on glass, wood, or paper, is obtained as follows:—About half an ounce of common glue, which has been a day before soaked in water, and some candy sugar, with half an ounce of gum arabicum, and three ounces of water, are placed in a small bowl over a spirit lamp, and continually stirred till the composition thoroughly boils and dissolves, and the mass becomes thin. When coated with a small brush, and left to dry, the tickets, when moistened with the tongue, will stick with the greatest tenacity.

**To Correspondents.**

**ASHBURTON.**—The term "whole-plate" describes a plate of 8½ inches by 6½ inches. The term had its origin in the days of Daguerreotype. The half-plate was 6½ inches by 4½ inches; the third size was 5 inches by 4 inches; the quarter-plate 4½ inches by 3½ inches; the sixth size 3½ inches by 2½ inches; the ninth size was 2½ inches by 2 inches. These were all the usual sizes of which Daguerrotypes were taken. Extra sizes—such as 10 inches by 8 inches, 12 inches by 10 inches, &c.—were occasionally produced, but had no regular recognition.

**R. S. T.**—The reticulation is doubtless due to the collodion, and is probably due to the use of too weak solvents; that is, there is too much water present, the spirits having been insufficiently highly rectified. We regret that we cannot recommend any maker's collodion; but should think the plain negative collodion of most makers would serve. You may make a suitable collodion by following the formula given during several years in our YEAR-BOOK; but it is a troublesome process on a small scale. For use as a practical basis for the negative in place of glass you would require to use a much thicker collodion. The preparation of collodion which Mr. Woodbury and others have more than once described in the NEWS and YEAR-BOOK as leather collodion, having castor oil added to it, is best suited for the work. The examples you send are much too thin. Failing the use of the leather collodion, gelatine, in the manner we have often described, might be used for the transfer. A negative transferred to gelatine or collodion should be of the thickness of a piece of firm writing paper. If you get a fine sample of graphito it should be as fine and impalpable as it is possible almost for any pigment to be; but where it can be procured we cannot tell you.

**F. H., A CONSTANT SUBSCRIBER.**—There is no reason why an English photographer should not photograph the public buildings in Paris. Indeed, the best instantaneous street views of Paris we have seen were produced by an Englishman, Mr. Wm. England. 2. We fear that there are not many very special opportunities for a country visitor to see anything important or novel in photography in London. He may visit the International Exhibition, and see a few fine examples of photography in the photographic department there; and he will see many fine pictures in the picture galleries. He may see something by visiting the specimen rooms of some of the leading photographers, and he should pay a visit to the National Gallery in Trafalgar Square, and also the National Portrait Gallery.

**G. COOPER.**—There will be no medals given at the next exhibition. None of the conditions as to reception of pictures have been published yet, nor, so far as we know, even determined.

**FERE.**—We believe that Mr. Meagher, of Southampton Row, manufactures the combination printing frames.

**W. H. W.**—We cannot understand the matter at all. It is inexplicable. You do not send a copy of the original letter to which the angry reply is sent.

**IONORAMUS.**—Your first requisite in producing transparencies by the wet process will be a suitable copying camera. If you have access to our volume for 1871 you will find it described in an article on page 449, and many other details there given. A useful article on the subject also appears in our YEAR-BOOK for 1868. If you cannot refer to these, we may here briefly indicate the style of thing required. You will require a camera extending to double the focal length of the lens to be used; that is, if you use an ordinary quarter-plate lens, which has a focus of 6½ inches, your camera must extend 13 inches. You will also require a box of the same size as the camera, with each end open; in one end a groove to hold the negative, whilst the other end is placed close to the lens. The light of a north sky must pass through the negative, which must be duly brought into focus. All the working details of the ordinary wet process will serve. Use a developer with ten grains of the iron salt and twenty minims of acetic acid. After fixing and washing, tone with a solution of chloride of gold two grains to the ounce.

**OXONIENSIS.**—For beginning in landscape work, you cannot do better than obtain a bellows-bodied camera and lens to take views of about 7½ inches by 5 or 5½ inches. The lens you mention will do very well. You will be safe with almost any of the commercial collodions. They will answer your purpose much better than attempting to make your own.

**C. A. OWEN.**—No. 3 on your list will answer your purpose best.

**CHARLES WHITING.**—Thanks In our next. Several Correspondents in our next.

**METEOROLOGICAL REPORT FOR JULY.**

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

Date.	In shade. Morning.	In Shade. Noon.	Night.	Temp. at Noon in Sun.	Direction of Wind at 9 a.m.	
1	62°	63°	58°	—	S.	Drizzling rain all day
2	66	60	61	—	S.	Drizzling rain a.m. and p.m.
3	63	64	59.6	—	S.	A little rain a.m. and p.m.
4	61	61	59	—	S.S.W.	Rain this evening
5	58	61	58	91	W.	Rain early this morning. Generally sunny
6	62	67	55.8	100	W.N.W.	Fair and sunny
7	64	68	64	110	S.	Fair and sunny. Close and sultry this evening. Distant thunder p.m.
8	66	66	59	—	S.S.E.	Fair. Gloomy. Distant thunder
9	62	68	63	—	S.	Fair. Gloomy. Close and sultry
10	66	69	62	112	W.S.W.	Fair and sunny. Sultry
11	61	66	60	—	W.	A little rain at night. Cloudy all day
12	60	72	61	120	—	Fair and sunny
13	64	68	65	—	S.W.	Gloomy all day. Heavy rain at night
14	63.5	70	65	118	W.S.W.	Fair and sunny
15	67	67	61.5	118	S.	Fair and sunny
16	68	78.5	72	121	—	Fair and sunny. Heavy thunder clouds occasionally
17	70	76	65	108	W.S.W.	Fair and sunny
18	72	76	71	119	S.	Fair and sunny
19	72	76	69	118	W.S.W.	Fair and sunny
20	66	70	66	106	S.S.E.	Rain, thunder, and lightning early this morning. Fair and sunny during the day
21	63	68	60	109	W.N.W.	Rain a.m. and p.m.
22	60	68	66	111	W.S.W.	Fair and sunny
23	61	69	63	105	S.	Fair and sunny
24	63	67	64	—	S.	Rain a.m. and p.m.
25	63	69.8	63	99	S.W.	Rain a.m.
26	62	67	62	103	S.	Rain morning and evening. Clear during the day
27	63	66	64	108	S.W.	Rain early this morning. Sunny all day
28	58	64	57.7	105	E.	Sunny during the day. Thunder and lightning, with rain, this morning
29	60	70	63	116	N.N.E.	Fair and sunny
30	62	71	63	118	S.	Fair and sunny
31	63	60	63	—	S.W.	Rain all day. Strong wind this evening

From the above data we deduct the following:—

	Mornings.	Noons.	Nights.
Maximum temperature	72°	78.5°	72°
Minimum ditto	58	60	55.8
Mean ditto	65.8	67.7	62.7
Maximum temperature in sun	—	—	—
Minimum ditto	—	—	91.0
Mean ditto	—	—	110.24
Mean temperature of all determinations in shade	—	—	65.4
Number of days on which rain fell	—	—	15
Number of days on which it was fair	—	—	16
Number of days on which it was fair and sunny	—	—	12
Number of days on which it was fair and gloomy	—	—	4

Prevailing wind S. and W.S.W.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.  
PHOTOGRAPHY IN MID AFRICA—HOW TO TEST DRY ALBUMEN—ASTRONOMICAL ENLARGEMENTS.

*Photography in Mid Africa.*—We are glad to hear that the expedition sent out by the Viceroy of Egypt into the interior of Africa, under the command of the well known traveller Gerhardt Rohlf, is employing photography largely in taking records of the scenes the travellers pass through. Too much importance cannot be given to the camera in exploring expeditions like this, and if we but call to mind the few pictures taken during our own Abyssinian expedition some years ago, the interest of photographs taken in these wild regions is at once made manifest. The wilderness of rocks and torrents, with scarcely a tree the whole distance, was vividly portrayed in the pictures we refer to, and a glance at half-a-dozen of these conveys a more correct idea to the mind of the nature of the country than a whole volume of description could do. The only effective manner, indeed, of showing people at home what these wild regions are like, and to impress them with a true notion of the primeval forests and dismal swamps, gigantic lakes, and native villages of Mid Africa, is to lay before them reproductions of the scenes themselves as they have been secured in the camera. We have already mentioned the fact that Gerhardt Rohlf is accompanied in his travels on the present occasion by a Berlin photographer of repute, M. Remélé, whose practical investigations, especially in the matter of developers, are known to most of us. He seems to have been working hard with his apparatus, and securing a large number of interesting pictures, which will doubtless be highly prized when they reach home. A letter from a member of the expedition says:—"During our journey through the desert our skilful photographer Remélé took numberless landscape and ethnographical pictures, including a fine series of a fallen temple which is in our neighbourhood. The hieroglyphics upon the portals, which have been carefully rendered, will suffice for Eastern scholars to discover the epoch of its building." Colonel Gordon's military expedition, which is also in Central Africa, charged by the Viceroy with the suppression of slavery, has, we fear, no such valuable assistant on his staff, although apparatus for surveying and mapping have not been forgotten; and it was only last week that further scientific assistance, in the persons of two young Royal Engineer officers, was sent off to Egypt. We cannot but regard it as a great mistake that a camera and some dry plates should not have had a place among the apparatus taken out, so that some interesting records might be secured, alike valuable and interesting to people at home, as to the travellers themselves.

*How to Test Dry Albumen.*—Albumen, and egg albumen especially, is often adulterated with gum, dextrine, syrup, &c.; and although photographers, as a rule, only employ the fresh material by breaking the eggs themselves, and thus being assured of its purity, it may be well for them to know how to test albumen that they may purchase commercially in a dry state. M. Herberger, who has been investigating the subject thoroughly, has lately given his experience of the matter. The sample to be examined should be digested with cold or lukewarm water, and if white lumps are left undissolved on stirring, the substance has been too quickly dried, so that the albumen has been converted into the insoluble modification. Water is added, so that the solution may contain at most twelve per cent. of albumen, and then acetic acid is dropped in until neither precipitate nor turbidity is perceptible; alcohol is then added, and if there happens to be any gum in the albumen it is precipitated. Dextrine and analogous bodies are detected by the production of a blue colour with iodine solution. Egg albumen, if good, should be

transparent, of a pale yellow tint, and free from blisters, which are often present in partially coagulated samples.

*Astronomical Enlargements.*—Professor C. V. Zenger, of Prague, has written to Mr. Glaisher to propose a method of enlarging solar and lunar photographs, so as to correct the spherical aberration, and he gives some advice on the forthcoming transit of Venus operations. He thinks it will be perfectly useless to photograph the phenomenon at the moment of contact, because accuracy is entirely destroyed by the effect of the interference, and thinks it would be better to have the passage photographed at intervals, so as to ascertain exactly the moment at which Venus passes through a determined meridian on the sun's surface. Prof. Zenger has been successful in producing some very big astronomical enlargements, and thinks that one might obtain a magnified image of the transit of Venus measuring 200 to 250 inches. In some lunar enlargements, measuring eighty to one hundred and ten inches, which he will exhibit at the British Association meeting that will take place next week, there are to be seen many details unobservable by the naked eye. Slight shadows and ridges in the craters of the moon are rendered as sharp and as definite as they can be seen in the clearest and driest winter evenings with the most powerful telescope. Some moon pictures which were originally three inches in diameter, and were enlarged by Mr. Brothers, of Manchester, to eleven inches, have been amplified by Professor Zenger to 110 inches, gaining rather than losing definition. His method of enlarging to these grand dimensions is as follows. He gets, in the first instance, very sharp images by using a parabolic speculum, the rest of the spherical aberration being destroyed by a very fine aplanatic lens of Steinheil, with negative focal length. In this way solar images with spots on them were obtained of the greatest sharpness, with *faculae*, willow leaves, and a most sharply-defined gradation of penumbra, the diameter of the sun's image being from twenty to twenty-four inches. He then conceived that the remainder of aberration in the images might be easily destroyed by photographing with lenses whose remainder of error was opposite to that of the photographing speculum or reflector; and he tried the experiment, employing an opera-glass, somewhat over-corrected for the purpose, with great success. At a recent meeting of the Royal Astronomical Society some impressions on paper of Prof. Zenger's enlargements were shown.

## THE PRACTICAL PRINTER IN AMERICA.

## III.

PROCEEDING to describe the preparation of the printing bath, we find that our practical printer, without discussing theoretical considerations, gives his verdict in favour of the mixed baths first described in our pages some years ago, which were at the time the subject of some warm discussion. Besides adding nitrate of soda, it will be noticed that carbonate of silver is kept in the solution, which will have the double effect of keeping the solution neutral or slightly alkaline, and of removing discolouration of the solution. The term *sal soda*, used in one of the paragraphs which follow, is the American colloquialism for carbonate of soda:—

"In the making of the bath, both good nitrate of silver and water are required. In all cases where pure water is required, filtered rain or clean ice-water will answer.

"To make a bath of 60 ounces of solution, and 40 grains strong of nitrate of silver to the ounce, the number of grains of silver required would be 2,400 grains, or 5 ounces. Take a large, wide-mouth bottle, and add 60 ounces of pure water thereto. Now carefully weigh out 5 ounces of good nitrate of silver and add it to the water in the bottle. Dissolve thoroughly by repeated shakings of the contents of the bottle, which is very easily done, without spilling the liquid, by holding the top of the bottle firmly

with the left hand, and revolving the bottom in a circular motion, in a steady and even manner, with the right.

"This bath is called 'plain nitrate of silver bath,' because of its being composed simply of nitrate of silver and water.

"This bath is used by a great many excellent photographers throughout the country, except that the strength of it differs, sometimes being greater, and then again often less than the strength given above.

"Mr. H. T. Anthony, of New York, was the first to advise the use of alum in the printing bath, and since the discovery of it for that purpose it has become quite universally used. It is, indeed, the best thing that can be added to the bath to give brilliancy and richness of tone to the prints. The theory of the alum, as being an improvement when used in the printing bath, is as follows:—The alum hardens the surface of the albumen paper when it is floated upon a silver bath containing it, so that the solution is kept more on the surface, and when the paper is quickly dried the resulting prints appear very brilliant, printing finely, especially in the shadows, and are more easily and better toned and fixed, and the final washing is more likely to be thoroughly done. A small lump of alum is placed in the funnel through which the bath is filtered, and the solution, as it filters, will take up the quantity it needs.

"Mr. John R. Clemons has recommended the use of glycerine in the printing bath, in the proportion of 1½ ounces of pure glycerine to every 16 ounces of solution. It has been used most successfully by many photographers, and it is especially a good thing for his brand of paper, when it is floated for the space of one minute on a bath of 30 grains (during the summer time) of nitrate of silver to the ounce of water.

"Sal soda is often added to the silver bath in the proportion of an ounce of a saturated solution of the soda to a bath of 60 ounces. On adding this, the bath will immediately turn milky, and after the solution has been thoroughly stirred it should be allowed to settle for awhile, and then filtered into another bottle before use, leaving the carbonate of silver (the deposit) in the first bottle. When through silvering the paper, pour the solution back into the bottle where the deposit is, and again shake the contents. In the morning the solution will be thoroughly clear, although the bath may have been very much discoloured when it was poured into the bottle the night before.

"Always let a sediment be in the bottle, and every other day add a few drops of the soda solution to the bath. Keep on 'adding solution' made up as above. A few ounces of the solution should be added to the printing bath every night after use, so as to keep the quantity up to a certain number of ounces.

"I have used a bath prepared as above for eight months, and although the bath, when poured from the silvering dish at night, was often as black as a coal, it never failed to be clear in the morning, if there was a sediment on the bottom of the bottle.

"Citric acid is also sometimes added to the printing bath, in a greater or less degree, according to the time the paper is required to be kept, for this is principally the reason why the acid is added.

"When the paper is only required to be kept a day or so after sensitizing, so as to prevent it from turning yellow by being kept over-night, on account of a sudden storm, &c., the solution is made a very little acid, viz., a few drops of a solution of citric acid 20 grains, water 1 ounce. If the paper is desired to be kept white for a longer time than a couple of days, then more of the acid should be added. Fume fifteen minutes. The paper will print a little red, but it will most probably be very rich, although this will be according to the quality of the negatives, &c.

"The 'citric acid printing bath' should be tested every morning before using it, to ascertain the degree of acidity.

Never let your bath be acid with nitric acid unless it is very, very slightly so, as the prints, besides being of a poor (photographically considered) red colour, are very liable to be weak and flat.

"Nitrate of ammonia is very often added to the printing bath in the proportion of as many grains of the nitrate to the ounce of water as there may have been grains of nitrate of silver added. After adding the nitrate of ammonia to the printing bath, make slightly alkaline with liq. ammonia.

"Sunning the bath for about half an hour or so after the nitrate of ammonia has been added, and the solution made alkaline, is a good plan. Filter before use. I will here give a few formulæ for baths for printing, which I have used, and know to be excellent:—

No. 1.—Crystal nitrate of silver ... ..	40 grains
Nitrate of ammonia... ..	35 "
Filtered rain water ... ..	1 ounce
Saturated solution bicarbonate of soda, about ... ..	8 to 10 drops,

or enough to make the bath slightly alkaline. In place of the sodium, liq. ammonia can be used equally as well. Make up a sufficient quantity, and before filtering through cottou, place a lump of alum in the funnel, about quarter the size of an ordinary butternut.

"The above bath is for summer use; in the winter both the nitrates should be increased.

No. 2.—Nitrate of silver ... ..	2½ ounces
Nitrate of soda ... ..	2 "
Glycerine ... ..	3 "
Pure water... ..	40 "

Make it a little alkaline with aqua ammonia. This bath is very good indeed for the Clemons brand of paper, and can be used also with the Hovey brand; but a bath made as below is better for this particular paper, viz., the Hovey:—

No. 3.—Nitrate of silver ... ..	30 grains
Nitrate of ammonia... ..	30 "
Pure water ... ..	1 ounce.

Make it a little alkaline with aqua ammonia, and when about to filter the solution place a small lump of common alum in the funnel, or, if you prefer, add a grain of the alum to every ounce of the solution. The latter is probably the best. The alum, if added in this way, should be added before the bath is filtered.

"Float the paper, being sure that it is a little damp beforehand, from twenty to thirty seconds; draw over a rod, and blot off the superfluous quantity of silver that is still on the paper, between large sheets of white bibulous paper. Dry quickly and thoroughly, and fume ten minutes.

"The above formulæ and modes of working are for summer use, but for winter the temperature of the solution should not be below 50°, and the strength of the nitrates should be increased as well as the time of floating. Print, in the winter, in the printing room under glass, and keep the temperature of the room not below 50° or above 60°.

"There are some photographers who prefer an acid printing bath to an alkaline or a neutral one, because the resulting prints are red, and the red tone is more easily obtained (?), so they say.

"If the bath is acid with nitric acid the result will not be so fine as it would be if it was acid with citric acid, because, if the bath was any more than very slightly acid with the nitric, the paper floated upon it when printed will have, as above said, a disagreeable red tone to it, often being weak and flat. The best results are obtainable with a bath which is either a trifle alkaline or just neutral. A good way to regulate the alkalinity of the printing bath is to observe how the paper prints, and then act accordingly. If it prints too blue, a drop or so of nitric acid should be added to the bath; if it prints too red, then add a few drops of liquor ammonia. In testing this way,

however, the printer should be sure that the paper is properly fumed, and that the results are not occasioned by poor judgment in fuming. Place a piece of blue litmus paper into the solution before you commence to 'doctor' the bath, and note the exact colour it turns.

"Nitric acid should always be added to the printing bath when it is not desired to make the solution acid for the purpose of printing, but only to lessen the alkalinity of the bath."

### AMERICAN CORRESPONDENCE.

THE NATIONAL PHOTOGRAPHIC ASSOCIATION AND ITS CONVENTION IN CHICAGO.

*The National Photographic Association and its Convention in Chicago.*—The convention and exhibition of the National Photographic Association for the year 1874, being the sixth of that useful institution, is now among the things of the past. All things considered, it was a grand success, and much good will result from it. I give you a synopsis of all that transpired, without waiting for details. The Association will issue a full report presently only to subscribers.

I arrived upon the scene several days before the opening, and found the photographic fraternity of Chicago all absorbed in their preparations for the great event. Local Secretary Hesler was busy superintending the erection of "space" for the exhibition of the pictures and of merchandise, and the decoration of the splendid exhibition halls. His assistants were busy receiving cases of goods in great numbers from all directions, and the scene was a most animated one.

I visited several galleries, and found the work of preparation going on with like vigour. The stockdealers, too, were vying with each other to see who could make the best appearance, in order to attract the photographers. This pleasant spirit was kept up during the whole week, as I can testify from pleasant personal experience.

Tuesday, the eventful day for the opening of the Convention, arrived, and promptly at ten a.m. President Bogardus sounded the gavel, and proceeded with the business of the association. After the address of welcome by Local Secretary Hesler, and the response of the president, routine business was taken up. The report of the executive committee was an interesting one, as it gave the doings of that body between conventions, and made several important suggestions, one being with regard to the election of officers, and the other concerning the failure of the members to pay their dues, and the consequent debt of the association. The treasurer reported the association \$3,556 in debt. His accounts were referred to an auditing committee, and reported correct. As recommended by the executive committee, preparations were now made for the election of officers. Messrs. Landy, Hall, Knight, Southworth, and Fitzgibbon were appointed as a committee to make nominations, to report at the afternoon session. They were instructed to report a multiplicity of candidates for each office.

Tuesday afternoon was devoted mainly to discussions on photographic practice, Mr. E. M. Collins taking the lead on the "Causes of the Discolouration of Prints." He was followed by Messrs. Bowdish on "Lighting and Retouching," Lockwood on "Making Good Pictures," Rulofson on "How to Push Business," Webster on "Manipulation," Loomis on the "Dignity of Photography," Hough on "Art Education," &c. The remarks and addresses were all models of terseness and practical usefulness.

The report of the nominating committee followed. Tellers and judges were then appointed for the election fixed for the evening session, and the tellers were instructed to prepare tickets and distribute them. All this preparation was made, instead of the election being held as heretofore, in order to prevent the insinuations so prevalent that the elections were not conducted fairly.

Mr. Bogardus peremptorily declined serving another

year as president. Mr. Bell made an address eulogizing Mr. Bogardus for his faithful service in behalf of the association, and in favour of Mr. Rulofson for president. The session closed about six p.m., and as the members dispersed, for the first time they learned of the dreadful fire which had been raging near by for over two hours. The smoke was flying in dense clouds over the exposition building, and caused great consternation all around. Great fear was entertained that the sixth exhibition of the National Photographic Association was doomed, and that before long the thousands of beautiful photographs displayed would be in ashes. Certainly no fashionable assemblage gathered there as was expected to see them, and all any of us could do was to watch and wait. Now the wind would drive the flames over us in fearful sheets, and following a rain of sparks and burning wood. At midnight it was thought best to remove many of the goods, and several exhibitors, desiring to be on the safe side, took the precaution to place their pictures, &c., out of danger.

In the morning we were delighted to find the building unharmed. The goods removed were replaced, and in a few days the exhibition halls looked as bright and beautiful as on the day before. But the fire had broken the spirit of enthusiasm, and there was a general anxiety to get away. However, those who did not flee the city, gathered together in the morning, and business was proceeded with as usual. But the backbone of the convention and exhibition was broken.

Wednesday morning the first order of business was the reading of the report of the committee on the progress of photography. This was followed by the appointment of a committee to fix the location for the next convention, and then Mr. W. H. Rulofson made a stirring appeal to the convention to remove the debt then, there, and now. He was followed by others, and it was resolved to take up the matter on the morrow. Other routine business followed. In the afternoon, Mr. D. H. Cross, the skilful operator for Mr. C. D. Mosher, of Chicago, and a gentleman well known by his inventions, made an address on general photographic practice, and he was followed by Mr. C. E. Meyers, in an essay on photographic screens, which was elaborately illustrated by models. Minor practical discussions were entered into, and then Mr. John R. Clemons gave one of his inimitable "talks" on photography in general, and some branches of it in particular. He then answered the catechizing of the members until time for adjournment. The day was intensely hot, and was a fair test of the earnest desire of the visiting photographers for knowledge pertaining to their work.

The evening was devoted to the election. The polls were open from seven p.m. to nine p.m., the tellers and judges being promptly at their posts. The votes were deposited rapidly, only a few attempting to vote without first paying their dues. All such attempts were foiled by Treasurer Moore, whose very impressive appearance reminded the gentlemen of their first duty before voting. For the first time in its existence, the National Photographic Association held its election by ballot. The result was nearly the same as heretofore, and it is hoped that all croakings about "unfairness," "manipulation," &c., will for ever cease, and that all good members will accept and support the officers who have been elected. The result of the election was as follows:—

*President*—William H. Rulofson.

*Permanent Secretary*—Edward L. Wilson.

*Treasurer*—Albert Moore.

*Executive Committee*—W. Irving Adams, A. Bogardus, A. Hesler, V. W. Wilcox, I. B. Webster, J. W. Black, W. H. Rhoads.

*Committee on Progress of Photography*—A. S. Southworth, W. H. Sherman, J. Landy, A. Gardner, Dr. H. Vogel, G. Wharton Simpson, M.A.

And one *Vice-president* from each state and territory.

Thursday morning Bogardus occupied the

chair, and received the report of the tellers. He then made his closing address, and welcomed his successor to the chair amid great applause. Mr. Rulofson made an address which won the whole convention over to him, and we could see by the faces of those present that they meant to support him. He will prove a most worthy incumbent of the office, which, he said, he considered "next in honour to that of the presidency of the United States."

Mr. Loomis offered resolutions eulogizing and thanking President Bogardus for his service. The permanent secretary and treasurer elect being called upon, each made a brief address.

To Mr. W. W. Gillis, Rochester, N. Y., was awarded the gold medal for the best display of frames; and to Messrs. Robinson and Cherill, of England, the gold medal for the best display of photographs from England.

Mr. Bell now moved that the subject of the debt of the association be taken up, and made an address on the subject. He was followed by others, when time for adjournment arrived. President Rulofson said the debt would be made the order of business for the first half hour of the afternoon session.

Mr. Clemons, chairman of the Scovill and Holmes Medal Committee, reported that the committee had awarded the Scovill (gold) medal to Mr. W. G. Entrekin, Manayunk, Pa., for his oscillating enameller; and the Holmes (silver) medal to Mr. L. V. Moulton, Beaver Dam, Wis., for his improved photo washer. Adjourned.

As announced, the first half hour of the afternoon session was devoted to the debt question. President Rulofson made a strong appeal for its removal, and others spoke on the same score. Many contributions then flowed in; a large demand was made for tickets in the "mammoth offer" enterprise, and about twenty were made life members, the whole amounting to nearly a thousand dollars. For a first effort this was very handsome. Mr. Bowdish gave two of his camera stands, which were quickly purchased; Messrs. Anthony and Co. gave a large camera box and stand, and there were several other gifts, which brought out the crowning one from Mr. Rulofson, of all the elegant pictures which he had on exhibition, and which, he announced, he would sell to the highest bidder in the evening. The permanent secretary, not knowing what Mr. Rulofson's auction sales would amount to, agreed to give one dollar more towards the debt, on a risk. One thing was most convincing, and it was worth more than all the money to see it, namely, that the members of the National Photographic Association value it, appreciate and see the good it is doing, and are determined it shall not fall. We congratulate them on their wisdom.

The committee on location for 1875 reported in favour of Boston, with Mr. J. W. Black for local secretary. Mr. Black was present, and made graceful acknowledgment, the usual promises, &c.

Mr. J. H. Tomkins, Grand Rapids, Mich., addressed the convention at length upon the status of the sliding-box patent, and was followed by Messrs. Southworth, Bell, &c.

A very pleasant feature of this session was the presentation to President Bogardus of a handsome solid silver pitcher and pair of goblets, as a token of their regard, by a committee of members of the association. Mr. Bogardus received it in his usually graceful style.

Friday morning, the first thing taken up was the reading of Mr. S. Lockwood's carefully prepared report on a Life Insurance League, and the formation of a Photographic Fire Insurance Company. These interesting matters deserve the attention of all photographers, and we recommend their careful reading. Both matters were referred to a new committee, to report next year.

Benjamin Freuch, Esq., made an address on the "debt," and was loudly applauded. Further effort was now made to remove the debt, and amid much enthusiasm the scene of yesterday was repeated, until the Permanent Secretary announced that enough tickets had been taken for the

mammoth prize to enable the drawing to go on. Mrs. Lockwood and Messrs. Mosher and Slee were appointed to prepare for the drawing. More subscriptions were then received, and the articles given yesterday were sold to the highest bidders. The Permanent Secretary reported that President Rulofson's auction last evening netted \$224, and therefore he had to acknowledge himself involved to the amount of \$225 towards liquidating the debt. This being the case, the whole amount now paid and promised was sufficient to wipe out the debt. Tremendous applause, and three cheers proposed by Mr. Bell. Happiness reigned, and the drawing for the mammoth prize followed. In one hat tickets bearing the numbers of the tickets sold were put, and in another hat blanks in equal number were placed, on one of which was marked the word "Prize." Two children then drew a blank and a numbered card simultaneously, under the charge of the committee. As drawn, the numbers were announced to the Convention, and for nearly half an hour continued, before Mrs. Lockwood said "423" — "Prize." The Permanent Secretary referred to his list, and announced that Mr. W. H. Jacoby was the owner of "423," and therefore the prize was his.

A committee was appointed to intercede with the Post Office Department, for better regulations for the mailing of photographs.

All routine business was now finished up, and President Rulofson bade farewell to the Convention.

Friday afternoon was occupied in practical discussions, vice-president Colonel H. D. Marks, of Texas, presiding. Addresses were made by Messrs. Collins, Elliot, French, Winsor, Husher, Libby, Hall, Webster, C. W. Hearn (author of the "Practical Printer"), Southworth, and others, when the convention adjourned to meet in Boston, July, 1875.

Thus closed one of the most eventful conventions ever held by any body, and the National Photographic Association left Chicago stronger than ever before.

The exhibition proper was a magnificent one, embracing nearly all classes of pictures from very many countries. As you will see, Messrs. Robinson and Cherrill carried away another medal. I wish some of your photographers would make the competition sharper for them.

EDWARD L. WILSON.

### THE MOON'S FIGURE AS OBTAINED IN THE STEREOSCOPE.

BY CHAS. J. WISTER.

[In the following remarks in the *Journal of the Franklin Institute*, Mr. Wister illustrates the distortion too common in stereoscopic views taken with the lenses too far apart, when an effect of exaggerated relief is sought.—ED.]

In a paper published some time since, in the *Cornhill Magazine*, and republished, September last, in the *Living Age*, entitled "News from the Moon," a singular argument, and to my mind a singularly fallacious one, is put forth in confirmation of the figure of the moon as deduced from the calculations of the continental astronomer, Gussev, of Wilna. This article referred to is without signature, but, as the author alludes to his correspondence with Sir John Herschel, he no doubt speaks *ex cathedra*.

The figure of the moon should be, as proved by Newton, an ellipsoid, her shortest diameter being her polar one, her longest diameter that turned towards the earth, and her third diameter lying nearly east and west, a diameter intermediate to the other two. Newton further found that her shortest diameter would not differ more than sixty-two yards from her longest—an insignificant difference, surely, in a body whose mean diameter is about twenty-one hundred miles.

Gussev, however, comes in at this point with an assertion based upon measurements of De la Rue's photographic copies of the moon at the extremes of her librations; and upon ocular demonstration derived from viewing

these different perspectives of the moon's image combined by the aid of the telescope, undertakes to subvert his great predecessor's theory, and to substitute one of his own, founded on this very unreliable testimony. He asserts not only that the moon is egg-shaped, its smaller end being turned earthward, but that the point of this colossal egg rises seventy miles above the mean level of its surface. Now it is to the proof of this as derived from stereoscopic evidence that I take exception for reasons hereinafter set forth.

The stereoscopic views of the moon are, as already stated, taken in the opposite stages of her librations, in order to obtain greater differences of perspective than would be obtained if taken in the ordinary way, where the separation of the two pictures corresponds with the average distance between the eyes of adults—four and a half inches; for this, it is evident, would give no more spheroidal appearance when viewed through stereoscopic glasses than is obtained by viewing her by unassisted vision, in which cases she appears as a disk only, and not as a sphere. With the same object—that of increasing the stereoscopic illusion (for illusion only it is)—it is not uncommon for photographers, when taking stereoscopic views of distant scenery, to avail themselves of the same means—that of unnaturally increasing the base of operations—and thus effecting a much greater apparent separation of the various planes of distance than really exists. The effect of this is to distort the picture painfully, advancing the middle distance boldly into the foreground—similar points being combined by the stereoscope much nearer the eyes than if the pictures had been taken in the normal way—whilst the foreground is seen so near, that one feels it in his power almost to reach it with his hand. Another and more objectionable feature of this exaggerated perspective effect is that all near objects are dwarfed; men become pigmies; imposing mansions are reduced to baby-houses, and lofty trees become insignificant bushes—the reason being that these objects, though seen at points much nearer the eye, subtend, nevertheless, the same visual angles as those seen at more distant points—points corresponding with their true position in the landscape—for the photographic representations of them are no larger, and therefore appearing nearer, and yet subtending no greater visual angles, the impression upon the mind is that of smaller objects. Every one, I think, who has viewed stereoscopic pictures of distant objects, combining middle distance and foreground, must have witnessed this distortion.

Now let us apply this principle of optics to De la Rue's exaggerated stereoscopic perspectives of the moon, and what is the result?

Sir William Herschel says, in illustration of the effect of stereoscopically combining images of our satellite taken at opposite stages of her librations, "it appears just as a giant might see it, the interval between whose eyes is equal to the distance between the place where the earth stood when one view was taken, and the place to which it would have been removed (the moon being regarded as fixed) to get the other." Now this would all be very well, provided the picture produced were for the use of giants formed after the pattern proposed; for they would see the stereoscopic image under exactly the same circumstances that they would see the moon herself in the natural way with their widely separated organs—no greater change being required in the direction of the optic axes in combining similar points of the two perspectives than is required in viewing corresponding points of the moon's surface by unassisted vision; but when these exaggerated perspectives are presented in a stereoscope to finite beings like ourselves the effect is magical indeed. Then do near points of the moon protrude in a most alarming manner, threatening to punch us in the eyes, the whole presenting the appearance of an unusually elongated turkey's egg. Neither the modest sixty-two yards of the immortal Newton, nor the more pretentious seventy miles of

Gussew, would satisfy her claims now: nothing, indeed, less than several thousand miles would represent the difference between her longest and shortest diameters thus distorted.

Indeed, for a pretty scientific toy, with which De la Rue has supplied us, this distortion of the moon's image is of little moment. The curious are, no doubt, more pleased with it than if it appeared in its true proportions—for figures generally are more admired the less nearly they conform to nature's lines—but that men of science, even great men, should accept this delusive and distorted image as a basis for serious investigation of the figure of our satellite, conscious of the manner in which pictures producing this image are taken—and, though forewarned, should not be forearmed—passeth my understanding. It is but another instance of the too great avidity with which world-renowned philosophers seize upon the most unreliable evidence from which to draw conclusions most important to science, thus shaking the faith of those who have hitherto looked upon them as infallible.

### PRINTING IN THE DARK.

REFERRING to the incredulity expressed at the French Photographic Society as to the continuance of the action of light upon isolated bichromated films, Mr. H. Baden Pritchard writes as follows to the *Moniteur de la Photographie*:—"I have read with some surprise your recent remarks upon the matter of carbon printing. 'Printing in the dark' is, with us, so common a practice that I was of opinion that the continuance of the action of light upon a film of bichromated gelatine, after it has been exposed to the action of the sun, was an accepted fact. It is the custom here, in the Woolwich Photographic Establishment, when a large number of impressions are required in a hurry, to only half print the pictures, and to preserve them in the dark for twenty or four-and-twenty hours before development, and then the printing is found to be complete. It is not a simple experiment, therefore, but a practical method by which we have produced a great number of prints.

"When M. Gobert did me the honour to pay a visit to Woolwich I showed him several specimens of the process. I exhibited to him, also, two prints which had been exposed half the proper time in the sun, one of which had been developed at once, and the other preserved many hours before development. The first was very pale, the second very vigorous. I believe that M. Gobert was satisfied in the matter, otherwise I should have been pleased to have demonstrated the fact experimentally.

"I have made a large number of experiments with isolated films, and have kept them for a long time in a moist atmosphere, and dry in vacuum; I found that when preserved in a desiccated state under the bell-jar of an air pump, the solar action progressed far more rapidly than in the presence of moisture.

"The reason why this mode of printing does not always succeed appears to me very clear: it is no doubt in the nature of the film itself, which has not, perhaps, body enough. In fact, one often hears unsuccessful operators say that if the impression is kept for some time, in lieu of gaining vigour, the whole mass of pigmented material becomes insoluble. The tissue employed in the War Department is supplied by the Autotype Company, and this may be preserved in winter time for a week or ten days in the same condition of sensitiveness. It is only in very hot weather, unfortunately, like the present, that it becomes insoluble after two or three days.

"If an impression preserved for some time during cool weather becomes insoluble, this proves conclusively that the solar action really does continue, or that the pigmented mixture has not been properly prepared.

"When the weather grows colder again, I should be happy to send you some samples of tissue to experiment with."

## PHOTOGRAPHIC PUZZLES: SHOULD THEY BE DISCUSSED MORE?

IN what manner may photographers generally best acquire all the secrets in their art? This is a question which should interest every one; but most of all that large section of photographers residing in provincial towns, away from photographic societies and from opportunities of personal examination of other work than their own. It should also interest even the most accomplished photographer with the best metropolitan opportunities of investigation. For despite the wonderful progress which the art has made, there are many secrets yet to be discovered, many riddles to be solved in connection with the art. Besides the many theoretical questions yet to be settled, there are many of a directly practical character which concern the working operations of every photographer, and which have hitherto been discussed in such desultory and fragmentary manner that no satisfactory or definite conclusion has been attained. Can exposures be shortened by the use of energetic developers in the wet process without risk of fog? Can the same result be secured by modifications of collodion or nitrate bath? What is the cause—or, rather, what are all the causes—of minute yellow spots in prints? What is the cause of pinholes when a perfectly new bath is used? What is the cause of streaky, irregular markings at one end of the plate in certain states of the collodion and bath? Is there a positive advantage in fuming sensitive paper with ammonia? These and a score of other questions have not yet been absolutely determined: the final word has not been said in relation to any of them.

These are, then, unsettled questions, worthy of discussion, which have not received the attention they deserve. Most of them have been discussed in some sort, but generally in a fragmentary and desultory manner. A frequent occasion of complaint is made by some photographers, of whom we may mention an example in a correspondent signing "Senex" in the present issue, to the effect that the practice of free intercommunication which was the main source of rapid progress in the art years ago, is dying out; that photographers are becoming more reticent and less liberal, keeping for their own purposes, or vending for a price, with conditions of secrecy, any especially valuable method they may discover. That the fact is so there can be little doubt; and it is, perhaps, not unnatural. In the early days of photography it was essentially an art-science, chiefly pursued by enthusiastic amateurs; and they delighted to interchange ideas with each other, giving and receiving aid, as scientific men and members of

purely scientific societies usually do. They had no thought of either keeping back or selling their experiences. As a rule, the ablest men, and those occupying the highest positions in the art, still communicate freely their modes of working, as our pages and society meetings attest. But photography has undergone various phases of change: whilst at one time the amateurs far outnumbered the professional photographers, now portraitists alone far exceed the number of amateurs devoted to the art. Photography has become a trade as well as an art-science. Improved methods possess a money value, and when preserved secret, or known to a limited number, give, or are supposed to give, to the initiated a commercial advantage over their less informed competitors. It is possible, doubtless, to say something in defence of the retention for profit, or sale for money, of secrets which have cost time and money; nevertheless, the practice is, fortunately, not common. It is certainly not elevating to the individual or the art. It is scarcely possible to secure a high art status for a profession which is supposed to depend much for success upon vendable secret dodges, rather than on the personal skill and culture of the artist.

But we cannot but think that the tendency to reticency and maintenance of secrets is often exaggerated. Many subjects are less discussed now, perhaps, than they used to be, from a certain supineness or indifference begotten of success. The ordinary processes of photography have attained such an even level of successful practice that it is for the most part not difficult to shunt many of the difficulties which cannot be overcome, and the busy professional photographer, who should be most interested in many of the questions to which we have referred, is content to let moderately well alone, and let doubtful matters "slide." Amateur photographers in this day are more deeply interested in dry processes, emulsions, &c.; and these are more actively discussed. But the great defect in much of the discussion of matters photographic, alike amongst professional and amateur workers, is a want of a systematic and exhaustive method. The full statement of experience on any one subject by many minds, each giving a clear and full statement of individual knowledge, would be invaluable on many subjects. In a recent communication Mr. Bovey very clearly pointed out an admirable method which might be adopted with the most beneficial results. We will here re-state his proposal for the purpose of emphatically endorsing it. Referring to the fertility of resource which usually distinguishes the skilled photographer, he says:—"What the result, then, if we culled such experiences in pages that should be devoted to the publication of puzzling conundrums, by the managing director, say by preference, of the NEWS? The problems to be stated somewhat thus: 'I have a negative with sky, by artificial means, so softly stopped out, that outlines of picture have nothing of scissors to show. How was the masking accomplished?' Brown knows all about the plan, and states how he has done it; Jones has been equally successful, although, in comparing methods, he works quite another way; Robinson has essayed to secure such results in many a trial, and burns to learn the secrets that lead to success; whilst all interested in the matter would enjoy opportunities of selecting for themselves the easiest; and ideas thus sown in fresh soil would propagate improvement, most certainly. Then failures might be introduced with a view of culling concealed principles from an examination of the proffered remedies. Fog, stains, stars, comets, together with those etceteras so familiar among photographers' woes, might be introduced in turn, and something new would be obtained from each subject under examination." We heartily commend such a course of giving and receiving all possible light upon many subjects of interest to all our experimental readers, and promise every aid we can offer towards rendering such discussions pleasant and profitable.

## THE NATIONAL PHOTOGRAPHIC ASSOCIATION IN AMERICA.

THE sixth annual convention of the National Photographic Association of the United States was held in Chicago, the meetings commencing on Tuesday, July 14th, and continuing all the week. A copious summary of the proceedings will be found in the letter of our American Correspondent; but there are one or two points worthy of comment which will especially interest many of our readers, especially those who believe that by the formation of some national union of photographers the status of the art and its devotees would be elevated, and their interests promoted. The proceedings of this convention certainly tend to confirm such ideas. The meetings were held under the shadow of a great calamity in the city. During the afternoon of the first day of the convention the second awful fire broke out in Chicago, and raged for many hours sufficiently near the neighbourhood of the meeting room to render the removal of goods and pictures from the exhibition desirable. They were replaced next day; but, as our correspondent states, the anxiety and alarm of the fire effectually crushed out all enthusiasm from the members, and spread a pall of gloom over all their proceedings. In spite of this, it is impossible not to be struck with the tone of staunchness to the association which prevailed, and the co-operative brotherhood which seems to have been engendered. It appears that the activity of the association had outstripped its means, and it was desirable that a debt should be cleared off. On the first appeal a sum of a thousand dollars was raised by contributions in cash and kind, and by some members compounding for life membership; and a second subscription reached a still higher sum, and enabled the executive to "wipe off the debt." One photographer, Mr. Rulofson, presented a fine collection of pictures which he had at the exhibition, which, being sold by auction to members, realized the sum of two hundred and twenty-four dollars; and the permanent secretary of the association, our esteemed correspondent, Mr. Wilson, having, before this action took place, pledged himself to give one dollar more than any sum which might be realized by it, at once announced his readiness to contribute two hundred and twenty-five dollars towards liquidating the debt. We mention this one instance as illustrating the spirit of liberality and earnestness which is at once cause and outcome of such conventions of men, with common aims and interests, which may be promoted by concerted action and interchange of thought.

The papers appear to have been interesting and instructive, and the exhibition a capital one. Messrs. Robinson and Cherrill taking the gold medal for the best display of photographs from England. It would be an interesting thing, by the way, if, in their next distribution of medals, the Photographic Society of Great Britain offered a medal for the best display of pictures from an American or foreign contributor.

### LAMBERT-TYPE.

THIS process, which is patented in France, and which, for some time past, has been offered for sale among photographers, our esteemed correspondent M. Lacan having recently referred to it and the effective results produced by its aid, has just been published in all its details by Dr. Liesegang, in the *Photographisches Archiv*. It is a method of producing enlargements, and the secret of the affair is, after all, a very simple one, consisting, indeed, in a plan of retouching which, in the finished picture, seems very elaborate, but which, nevertheless, may be carried out in a very brief period.

The enlarging is done by means of the carbon process, and although Dr. Liesegang enters into the matter at great length, there is little need for us to go through the details circumstantially. From the negative of small dimensions is produced a carbon positive, printed upon

pigmented tissue, which is developed on a good piece of patent plate glass. The strength of the positive, viewed by transmitted light, is deceptive, and therefore it is recommended that the impression be viewed with a sheet of white paper underneath it. This positive upon glass is put into an ordinary enlarging camera, and a piece of ground glass (polished side towards the cliché), and, if need be, a condenser, employed in front to condense the light and break it up again; or, as in Paris, a dark room suitably fitted up may be employed instead of the copying camera.

The large negative is then taken in the ordinary way upon a sheet of patent plate, and developed with iron, and fixed. But very little intensifying should take place, because in the retouching process sufficient vigour will be imparted to the cliché. The latter is finished in the ordinary manner, varnished, &c., and then taken into the retouching room to undergo the secret process which imparts to it the artistic excellence possessed by the Lambert-type prints. Like all other processes that depend upon retouching, it would seem as if the operator must be something of an artist in order to secure effective and agreeable results within the short space of half an hour.

The secret, then, is briefly as follows:—On each side of the negative is pasted a sheet of French vegetable paper. This is exceedingly clear and transparent, and it is sold in the capital under the name of *Papier Vegetal*. It must not be confounded with ordinary transparent papers, which are not fine enough for the purpose. A sheet of this vegetable paper, then, is coated at the borders with paste or glue, and placed over the collodion image, and another sheet of similar size is applied to the glass, or reverse side, of the negative. The paper must of course lie flat against the glass, and for this reason it is well to moisten the same slightly before it is applied. On drying, it will then stretch out perfectly flat.

The retouching is conducted by applying upon the paper upon the glass side of the photograph, powdered chalk or graphite, by means of a leather or paper stamp, covering with it the large transparent patches and broad lights. Upon the collodion side of the negative the face markings are equalized by the aid of a brush and Indian ink, and high lights are touched in where they appear necessary. No fine working is necessary in the matter, for the double filtrations of the light through the vegetable paper give so much softness, that in a short time the same effect is produced as if the negative had been carefully and artistically retouched throughout.

The large negative is finally put into an ordinary printing frame, and an albumenized impression taken in the ordinary way.

Dr. Liesegang states that the process has been purchased by many houses in Germany, and many of the results he has seen show that much finer results can be produced than by the methods of intensifying usually adopted by photographers.

### THE PRESENT UNSATISFACTORY STATUS HELD BY PHOTOGRAPHY.

BY W. BOVEY.

To fill the highest possible place in the world's estimation is an object which cannot be too eagerly sought after by honourable ambition; and he who has no recognized status to boast of might write himself down neglected indeed if his character, and the intellectual nature of his daily pursuits, are in strict unison with a somewhat indefinite respectability that, in its general make up, includes morality, skill, deportment, gold, silver, silks, woven wool, and spun flax, to meet the varying demands of society, whose tastes must be flattered with show to over-reach prejudices that run in separate grooves.

For several years past, photographers have had ample cause to complain on account of its social position, as unsatisfactorily viewed by outsiders, and numerous have

been the suggestions provided to teach how the coveted appreciation might be secured; and although each, from all others, in substance would appear widely to differ, the directions, when analysed, all tend to show that a strict observance of self-respect is the surest road to take when seeking the good opinion of others.

Without a cause there can follow no effect; and in obedience to this axiom, there must exist some reason for the social degradation of which photographers so bitterly complain. Nor need we indulge in vague speculation over this matter, as a brief notice of facts undeniably suggests that cheapness and what the world believes to be *ease of production*, have influenced public opinion to a certain degree, but have not, perhaps, lowered the status of photographers to its present humiliating position; such being, probably, in part due to peripatetic photographers whose studio is the road-side, whose patrons are chance passers-by, or the recent out-put of licensed houses, who, out for a lark, make it part of the day's sport to have their likeness taken. At fairs, races, watering-places—in a word, where crowds do congregate for purposes of pleasure—there is seen the ubiquitous photographer, varying in his outward appearance from a repeat of Bill Sykes the bold burglar, to a woe-begone swell out of luck; and it is to be feared that the public too often form their estimate of photography from an observance of these whining louts and lusty shouters, who do not scruple to make all claims they safely can on those who make themselves patrons; and however the errors thus entertained might be deplored, we may not cast a stone in anger at the innocent delinquents, they holding secure possession of an undoubted right to fill any vacant place in the scramble for the means of subsistence, without any necessity of considering the damage their pursuits inflict on the character of others, who, unhappily, have no means at hand to convince the world that there exists as broad a gulf which separates a cultured art photographer—an immeasurable distance from the road-side quasi practitioner—as is placed between a Millais or a Frith and the all but extinct manufacturers of pencilled profiles that are drawn, coloured, and delivered all for the sum of sixpence and moderately upwards.

The world, be it duly noted, rarely indulges in any but superficial reasoning, and its judgments are based on hastily glanced over premises; hence it equalizes the status of photography, simply because photographers have no distinctive sign to show that the skill required to make a good photograph has been acquired by much practice, patient study, and an application of those higher mental qualities that stamp a mind with the mark of intelligence. The chemist is but a mixer of drugs, if his sign-board does not make known that he is a qualified member of the pharmaceutical corporate body. A surgeon is but a setter of bones—a practitioner of midwifery—if, perchance, he neglects to add “M.R.C.S.” to his name plate. “M.A.” is a useful adjunct to the divinity of divines. And “F.R.S.” are letters most eagerly longed for by every man of science. Depend upon it there is associated with initialled marks of honour a mysterious degree of fascination, which induces an elevation of status that the world freely grants without making any enquiries.

For some unaccountable reason, photographers, whilst mourning over their unrecognized position, have overlooked their interests in this matter of corporate distinction. True, the proposal to found a corporate head has been mooted again and again; but it would appear that all argument has been quashed by the thought, “we have a parent society,” which, by the way, has done us good service; but membership is too freely offered to make such a subject of boasting. We need something more distinctive and broadly separate; some institution where membership would be regarded as the highest seat of honour, whose certificates might be accepted by the outside world as a certain proof of extraordinary skill and intelligence possessed by each legitimate holder. R.A. sets the status of

the princes of the artistic world on an unchallenged throne; F.R.P.S. would doubtless set photography on its proper and merited footing.

But apart from the question of status, of which the general public form the chiefest part, photographers have yet to see the necessity of adding to their desire of notice some respect for themselves; have yet to learn that status cannot be raised by internal jealousies and squabbling. Glance over the field as it now presents itself to every regretful observer. Men without natural powers of inventing ought but scurrilous words are abusing those who, in their day, have done our art good service. Our journals, of which we were once so proud, give, at least in more than one instance, signs of sharing in the growing degradation; and a contemporary, once respected for its advocacy of our art-science, has plunged into the mire of miserable lampooning, which has not even second-rate wit to excuse or recommend it.

If this unwise departure from the legitimate track is received favourably by photographers, of what use can it be to mourn an absence of status such as they can have no possible claim to? If the tone of journalism to which I have just referred is one that chords with any widespread sympathy, then must I reluctantly conclude that the world grants all the consideration we can reasonably expect or deserve. I would not, however, libel the practitioners of our art by adventuring on such a thought. We have black sheep among us—many, doubtless—but there still remain a majority whose aims are on the side of respectability and progress. The improvement of status we therefore ask as our due; and although this will scarce be tendered “at call,” there still remains to us the pleasurable consolation that what we at present lose of respect from outsiders will in future be paid up with interest, if meanwhile we keep steadily before us those lessons of duty we owe to ourselves and to those who generously map out new tracks on the boundless field of invention.

#### A WORD ON DEVELOPMENT.

BY WILLIAM HENRY WATSON.

Of the many operations in photography, from the coating of the cleaned plate with collodion to the finishing of the paper positive, none gives so much interest to the manipulator as the development; and in the still more numerous phases under which chemical actions manifest themselves there is not one so wonderful, so perfect, or so interesting as the simple development of a photographic picture. Yea, simple. The plate removed from the camera bears a film one uniform mass, without a mark or a shadow; and yet, by the one application of the developer, we see before us a picture, a truthful representation of the original. But to insure *all* perfection, something more is certainly required than a mechanical operation regardless of all thought. There is a certain amount of judgment necessary, according to the nature of the subject, and, further, the chemicals all in proper order. In this communication to your valuable periodical I wish to place before your readers an easy method of preparing the developer which, for wet plates, I am now adopting.

I have no doubt that others as well as myself have found considerable difficulty in keeping a large quantity of the iron developer ready prepared, in its proper condition, and in good working order. As has been before suggested, I use strong solution of protosulphate and acid. My proportions for this are as follows:—

No. 1.—Ferrous-sulphate	...	...	120 grains
Sulphuric acid	...	...	2 or 3 drops!
Water	...	...	1 ounce
No. 2.—Citric acid	...	...	300 grains
Water	...	...	500 „
No. 3.—Alcohol sp. gr.	...	...	0.80 graius

The solutions, if not quite clear, should be carefully filtered; by so doing we save considerable time after.

To prepare two ounces of developer, I simply have to measure out 120 gr. measures ( $\frac{1}{4}$ -ounce) of No. 1 and about a drachm of No. 2, a drop or two of No. 3, and add water to make up the two ounces. By using such concentrated solutions (1) we at one blow do away with the inconvenience of frequently having to use the scales and weights; (2) the developer is made in half a minute, while it would take at least five minutes if we used the weights; (3) I have found it to work well only five minutes after mixing; (4) this developer is clear, and requires no further filtration; (5) we can use it stronger or weaker, as the subject may require.

Supposing I wish to take a ramble out with my traps into the fields; I mix, before starting, into a half-ounce bottle or less, 120 gr. measures of No. 1 and 60 of No. 2. By so doing I have also less weight to carry, and anything taken into consideration in that line is always economy. To make a drachm of developer the same strength as that given above, take about 10½ to 11 minims of the mixed solution of iron and citric acid.

This developer brings the image out slowly, and finally we have a great deal of detail.

Whilst engaged on the analysis of some samples of iron ore, I found that a solution of ferrous tartarate is sensitive to the photo-actinic rays. I have floated bibulous and other papers on a solution of it, and exposed under negatives, and have distinctly seen the faint images printed on the paper. The action, so far as I have seen, is very slight, yet I should not wonder if some valuable matters connected with photography are some day brought out in the use of this salt. The solution of ferrous tartarate I prepared by precipitating from the ferrous sulphate by ammoniac carbonate, ferrous carbonate, and dissolving in the absence of the actinic rays by an excess of tartaric acid. This solution will of course contain ammoniac sulphate. I made it equal to about 20 grains of the tartarate to an ounce of water.

### CORRECTING PHOTOGRAPHIC DISTORTION IN ARCHITECTURE.

BY CHARLES WHITING.

HAVING recently to copy a number of Daguerreotypes of architectural subjects, in which the perpendicular lines were leaning to at the top (in some cases very badly), it became necessary to correct this very interesting distortion. The means employed to effect this object may not be generally known, and an account of which may, perhaps, be useful to some of my brother photographers; therefore I send it for insertion in the pages of the PHOTOGRAPHIC NEWS.

I found that by placing the Daguerreotype to be copied out of the parallel with the lens-board—or, in other words, putting the narrow end of the picture nearest to the lens—the distortion effected, to some extent, corrected the previous distortion; but not enough, and I could not get the picture sharp all over.

The lens I found best was one of Ross's wide angle doublets, which has great depth of focus and also great distorting powers (if I may be allowed to use the expression), which, in this case, proved very beneficial. But for all this I could not quite correct the distortion until I thought of a swing-back. The ordinary swing-back cameras have not sufficient "swing" for the purpose, so I set to work to construct one. My copying camera has a movable repeating back; this back I made to work on points at the bottom, or, in effect, "hinged it" in the centre of the top part. I fastened, by means of a few tacks, a thin strip of iron, which projected over the top of the camera, the strip of iron having a series of holes in it. I was enabled, by driving a tack through one or other of these holes into the top of the camera, to produce a swing to

any extent. I fastened a dark cloth over this arrangement to prevent any light getting into the interior of the camera, and the work was done.

I may, perhaps, here observe, that to get the picture sharp all over, I found it necessary to place the swing-back at about the same angle with the lens-board as the Daguerreotype plate is—the Daguerreotype plate, lens-board, and ground glass presenting angles similar to the letter V with a perpendicular line through the centre, thus  $\sphericalangle$ .

I find by using my camera as above indicated, I can stretch one end of a square plate to at least half as long again as the opposite end, with the greatest ease, and still have it quite sharp all over.

Having succeeded so far, I thought my trouble at an end; but, unfortunately, another difficulty presented itself, and that is, by correcting the distortion in some of the worst cases the subject became somewhat dwarfed, or shortened in height, but still having the same breadth. The only way I was able to get over this trouble was by making a transparency from the negative I had made previously, and stretching one side in the manner above described, and then making another negative from this transparency, and stretching the other side, so as to bring it square again. This is some little trouble, but, except in very bad cases, it is not necessary, as the dwarfing is hardly perceptible.

In my own experience I found the best way to get rid of reflection from the polished surface of the Daguerreotype was to completely cover the front of the camera with black velvet, having a hole in it for the lens to project through, and to build a tunnel of the same material up to the Daguerreotype, leaving a portion of one side open to admit the rays of the sun to shine through on to the Daguerreotype.

It is very important to place the Daguerreotype in such a position that the polishing marks run in the same direction as the sun's rays. But in the case of circular polishing marks it is better to copy them in diffused daylight.

I trust this brief description may prove of some slight assistance to some of my brother workers.

### Correspondence.

#### ALBUMENIZED PAPER.

DEAR SIR,—A firm supplying albumenized paper to the profession has recently issued a circular commencing with a statement that, to my mind, is scarcely accurate, and I think a few words necessary in reply, which, I trust, may prove beneficial both to those who undertake the manufacture of albumenized paper, and to those who have to use the same, as they come from a practical photographer who himself is an old albumenizer, and much regrets that many who now supply paper to the trade should betray such ignorance of the practical manner of treating the paper they sell, and, consequently, issue absurd nonsense to really practical men. The circular I allude to commences thus:—"Of the many things which photographers make use of in their daily work, there is none so little cared for in photographic journals as albumenized paper," &c.

Now, sir, I distinctly and emphatically deny such an allegation; for any one reading the journals representing the art in this country must confess that albumenized paper and albumenizing is a subject continually upon the carpet, and many able articles and useful hints are frequently published. If the manufacturers of the raw paper, and, especially, the albumenizers themselves, as well as the vendors of the article, read the journals more than they evidently do, they would not publish and circulate such remarks as are continually being sent round to practical men.

An albumenizing firm get a medal for their paper at an

exhibition, and naturally publish the fact to all the world; but were the various papers sent practically tested, or did the jurors judge (as the world is far too apt to do) by outward appearances? I would recommend my professional brethren to try the different papers in the market one against another, in the same baths and at the same time, and decide for themselves.

The vendors of albumenized paper certainly seem in an advantageous position—at any rate, we may judge so from the circular before me—for, after laying down a kind of proposition—viz., that albumenized paper may be considered as the “further elaboration of a simple product,” a statement which no one would wish to deny—it goes on to say that “it is to the latter class that the preparation of albumenized paper belongs, for this material is due to the further treatment of a simple product—paper—with albumen; and it is to the circumstance that the finished material always depends upon the quality of the first product employed that so much variation in its nature is due.”

Next follows a long list of grievances with respect to the raw material and its imperfect manufacture, which I shall leave the manufacturers themselves to answer, although I fear they will not think it worth their while; for I am told they are very rich and independent, and care very little what albumenizers, or even photographers, say about their manufactures.

Then follows a charge against photographers, and we find printed in italics these words, “who often charge it with defects which might be overcome by increased attention on their part.” This, of course, is true in some small measure, but it is the poor photographer, as the ultimate purchaser and consumer of the article, who has to suffer. He has to pay for an inferior article, has an immense deal of extra labour in making reprints, disappoints his patrons by unavoidable delays, and probably all because some albumenizing firm, that knows little or nothing of the practical working of the papers, is trying some new fad, instead of working steadily in one groove, thus supplying a regular article. A statement is next made, that “many photographers desire a very glossy surface to their paper,” &c.

Now, sir, doubly albumenized paper, unless done very skilfully, is often a failure, and it is a mistake for albumenizers to attempt second coatings before they have been successful in giving one good even coating, for we next read this remarkable sentence: “Moreover, one cannot very well demand, seeing that there is no other practical method of drying at hand than that of hanging up the prepared sheets, that albumenized paper with a single coating shall yield pictures from the top of the sheet of equal vigour to those printed on the lower portion, upon which there is so much more albumen.” In reply to this, I would say that it is a wrong practice altogether to pin sheets up by the corners to dry, and that albumenized papers might and can easily be made of an even thickness all over, and worked up to the very edge. All that is necessary is, after drawing the sheet from the albumen over a glass rod, or something similar, to lay it immediately upon a wooden roller of a proper thickness to dry. These rollers must not be too small or too large; experience will dictate the size, as the temperature of the room must be taken into consideration. This simple arrangement will get over this insurmountable difficulty on the side of the poor albumenizer, who, because some find fault with his work, feels he must punch away both sides, giving first a right-handed blow to the manufacturers of the raw material, and a left-handed one to the photographer, and thus escapes himself, or thinks he does. I trust, sir, after this article, we may have a circular announcing the abolition of pin corners, and paper evenly coated all over; if so, the writer of this article will feel himself fully rewarded for his friendly criticism.

The rest of the circular I intend leaving, except to state that I think it would be wise if firms supplying albumenized paper would give up issuing all kinds of formulæ, instead

of leaving it entirely to everyone's choice and practical knowledge. It seems to me unwise for a firm (perhaps representing no practical photographers, and scarcely ever, if ever, trying practically the paper they sell) to dictate how such papers are to be treated. Surely it would be best simply to state whether they are strongly or weakly salted, and not to advise photographers to fix highly albumenized paper in a hyposulphite bath of the strength of one to ten, or even one to fourteen, in order to avoid blistering. The remarks as to the silver bath are just as foolish and vague, as well as misleading. Any practical photographer would have given a direct, simple formula, suitable to the paper, and not such latitude as one to ten or one to twenty parts as directions for the strength of the silver bath.

Before concluding, I would ask the question whether some substance cannot be discovered that could be applied to the paper supplied by the manufacturers, so as to completely cover any imperfections in such manufacture, and also such a substance as shall take kindly to the process of albumenizing, so that the latter shall be entirely free from any defects in the former, and thus wipe away for ever this ground of complaint. Will some of our chemical friends inform us, and thus add a new discovery to our already productive art?—Yours truly,

GEORGE HOOPER.

Winwood House, 68, Cannonbury Park South, N.

#### A CHEAP STILL.

DEAR SIR,—I beg to send you the particulars of how I made a still, and cost, if you think it worth notice, as I see occasionally in the NEWS questions about stills.

Get a half-gallon tin case, 10d.; large tin saucepan, 1s. 6d.; eight feet copper tube, 2s. 1d.; soft solder, 1d.; total, 4s. 6d. Fill the tube with sand, and ram it tight; bend it in shape round and round can, which is easily

done, as it is very soft; make a hole in saucepan bottom, pass tube through, and solder it tight. Put can on a gas stove, filled with water, make a hole in the cork, and put other end of tube through. Then fill saucepan with water and light up. It will do a pint and a-half an hour. The tube may be purchased at any tinman's ironmonger.—Your obedient servant,  
AN AMATEUR.

#### ON THE ASSERTED INFLUENCE OF COLOURING MATTERS UPON SENSITIVE SILVER SALT.

DEAR SIR,—Absence from home has prevented me from replying earlier to Dr. Vogel's communication printed in the NEWS of 31st July. The statements made by the eminent German professor have taken the world by surprise, and are accounted of so much importance that the contemporary press, both in this country and abroad, are proceeding to theorize and draw deductions of a premature nature, founded upon the absolute verity of phenomena observed under very exceptional conditions. That this is the case I have only to refer your readers to the last few lines of the extract from the *Scientific American*, given in the same number of the NEWS, and entitled “Application of Dr. Vogel's Recent Discovery in Photography.”

Dr. Von Monckhoven and Mr. Carey Lea are well able to defend themselves, so I have only to answer the objection which Dr. Vogel raises against my own experiments with coloured glasses. He says:—"Experiments made without the spectrum can never be taken to contradict those undertaken with it, any more than experiments without collodion can be employed in combating collodion investigation." This simile is unfortunate, for Dr. Vogel compares ponderables with imponderables—or, rather, *matters with forces*. Now I contend that it does not signify how the yellow rays are selected or generated for the purpose of experiment—whether by the burning of sodium, which gives out rays of the same degree of refrangibility as those in the neighbourhood of the fixed lines D; or by screening off the superfluous solar rays by the interposition of an orange glass, as I had done, or by actual exposure to a pure solar spectrum.

I have tested by the very instrument used by Dr. Vogel (*spectroscope à vision directe*) the quality of the light transmitted by my orange glasses, and find them to be suitable for the end in view; and I see no reason to doubt the negative character of my results, particularly as they are in accordance with all previous observations. In short, I find it impossible to admit, with Dr. Vogel, "that dry bromide of silver is sensitive to the orange rays;" for, if so, what dark room could we work?

When presiding at the June meeting of the Photographic Society, I took particular notice of the degree of tinting apparent at the edges of Dr. Von Monckhoven's plates then exhibited, and they certainly did not appear to be too strongly coloured. Their clear definition and general excellence as spectrum photographs far exceed those which, through your kindness, I have been permitted to inspect as the work of Dr. Vogel.

In a matter of such paramount importance to photographers, I would venture to suggest that the question at issue be referred to a commission, and amongst British representatives of physical science it would be desirable to invite the aid of Professor Stokes, Mr. Norman Lockyer, or Dr. H. E. Roscoe, whose conclusions, individually or collectively, would carry great weight, and virtually decide the matter at once.—I remain, yours very truly,

*Shanklin, Isle of Wight, August 10th.* JOHN SPILLER.

#### INTERCHANGE OF EXPERIENCE AMONGST PHOTOGRAPHERS.

SIR,—It is a constant source of regret amongst photographers who remember the birth of the art, to notice the growing tendency to secrecy which prevails amongst the photographic fraternity, or, at least, a large section of it. Time was when the first impulse of the devotee of the science of the sunbeam, when he conceived a new thought, had a new experience, or made a discovery, was to publish it for the benefit of all working in the same direction; and as almost every one did the same, all were benefited. As regards their photographic knowledge, they followed the example of the early Christians with their goods: "they had all things common, neither said any of them that ought of the things that he possessed were his own." Now this is sadly changed. There are still noble exceptions, and, as a rule, the best men are the most liberal and communicative. But, in too many cases, when a photographer has hit upon a novelty in working or formulæ, an ingenious "dodge," or a good preparation, he is prepared to sell the secret "for a consideration"; whilst others, from selfishness or indifference, keep such "dodges" for their own use. Of course, such persons will say that they have a perfect right to please themselves, and look after their own interests, without impeachment. This is scarcely true in photography. Every person connected with the art is so largely indebted to many others for freely communicated information, that he is in a measure bound to pay the debt by reciprocal communication on his own part. There is not a photographer in existence, however much he may have acquired through his own dear-bought experience, who is

not indebted to the freely published hints of others for much more information than at first thought he would be willing to admit. It was by this freedom of intercommunication in former years that photography owed its rapid progress. It is to the interest of the photographic community at large that this freedom of communication should continue—or, rather, that it should be revived.

If photographers generally would adopt a recent hint by Mr. Bovey: taking a specific subject of interest, which is not well understood, and each one who possibly can, attempt to throw some light upon the subject from his own experience: if all would do this, all would be gainers; for each one would either learn something new, or be confirmed in something which he had individually observed, and the "process-mongers," as our American cousins call them, would be cheekmated.

As a commencement, I will suggest a subject. The practice of fuming sensitive paper with ammonia is, I am told, almost universal in America, whilst it is but comparatively little practised here. Is there a good reason for its practice there, or for its neglect here? When the process was first mooted, I tried it, and liked it—I got richer prints and shorter exposure—but by and by I got stains, and rapid discolouration of the paper; and as my operations as an amateur did not demand extensive printing, the fuming box got cast aside, and I have not used it since. Will any of your readers state their experience upon the subject? I am sure it will be interesting and beneficial if the subject be fully ventilated.

Let me add one word on the subject recently introduced by Mr. Hooper—I mean the elevation of the status of photographers. I believe that revival of this liberal freedom of intercommunication would do more than anything else to revive self-respect, and with self-respect of necessity comes elevation of social status.—Yours very obediently,

SENEX.

#### Talk in the Studio.

INVISIBLE PHOTOGRAPHS.—Photographs of the Prince Imperial of a novel kind were seized last week in Paris. By means of a chemical preparation they were rendered invisible on the card, but on being dipped in water they became clear and apparent.

TRANSPARENCIES FOR ENLARGEMENTS.—A correspondent says:—"I have to thank you for your kind replies to my queries respecting Mr. Carbutt's process for making albumen transparencies, as given in the last YEAR-BOOK. I find it much easier to work, more certain, and the results are superior to a process for which I have given £5 5s. I find that much of the perfection of the transparency depends on the collodion used as a substratum, which should be fine and textureless."

ROBBERY IN A STUDIO.—At Clerkenwell Police Court, Abraham Belkadare, a native of Senegal, West Africa, and perfectly black, was charged before Mr. Hannay with breaking and entering a studio, and stealing therefrom nine pairs of plated sleeve-links, two plated brooches, one gold brooch, three lockets, one albert chain, eleven pairs of gilt earrings, three odd studs, and other articles, the property of Mr. George Frederick Ham, watchmaker and jeweller, and photographer, of 130, Euston Road. Prosecutor said he had a studio, which was built of wood and glass, about eight or ten yards from the front door of his house. He was called by a police constable, and having examined his studio, he found two large squares of glass had been taken out. The jewellery had been taken out of two glass cases in the window. Four drawers had also been ransacked, as well as a desk. Mr. Hannay committed the prisoner to the Middlesex Sessions for trial.

PATENT LAWS.—In the House of Commons, on Tuesday the 21st ult., Mr. Crawley asked the Home Secretary whether her Majesty's Government were prepared to carry out such recommendations of the committee on the Patent Laws, contained in their report of 1872, as could be adopted without further legislative powers; and whether he would introduce in the next session of Parliament a Bill for further amending the Patent Laws in accordance with the recommendations of the

committee. Mr. Cross replied that in the opinion of her Majesty's Government it was better to deal with this matter, not piecemeal, but altogether; and that it was their intention to consider it fully during the recess, with a view to legislation next year.

**NEW METHOD OF ENGRAVING.**—At a recent meeting of the French Association for the Advancement of Science, M. Gourdon, of Lyon, described some novel facts which he had observed in the action of acids upon zinc covered with certain metals. Zinc plunged into dilute solutions of sulphuric, hydrochloric, and acetic acids, is attacked only at the points where other metals are present. The metals which produce this phenomenon with most intensity are cobalt, platinum, nickel, and iron. Ammoniacal chloride of cobalt renders it possible to perforate zinc with water containing only one ten-thousandth part of sulphuric acid. M. Gourdon applies these results to various procedures for engraving. By writing directly upon zinc with different metallic inks, making use of the most active, containing salts of cobalt, for the blackest parts, and passing it then into acidulated water, an engraved plate is obtained. To reproduce leaves or plants, they are soaked in solutions of metallic salts, and applied to the zinc, which is then treated with weak acid. The author has discovered a new kind of heliographic engraving, by transferring the silver from an ordinary photographic proof upon the zinc, which can be attacked by the acids in the parts where the silver has been deposited.

**AUTO TYPE REPRODUCTIONS OF EARLY ART.**—The *Athenaeum* is occasionally just to photography. It recently says:—"In the series of British Museum photographs lately brought to a successful issue by Mr. C. Harrison, under the sanction of the trustees of the British Museum, specimens of illuminations, miniatures, and early drawings, were unavoidably omitted. To render the collection of reproductions more complete, it is proposed to issue, uniform in size with the photographs already published, a series of photographs, executed by the autotype carbon process (which combines permanence with pictorial effect and faithfulness), taken from the manuscript treasures deposited in the National Library. The whole set photographed by Mr. S. Thompson, of which the first part is now ready for immediate issue, will embrace the principal European styles, and is calculated to be complete in six parts. The first part will contain twenty plates of full size specimens of work executed in England between the tenth and fifteenth centuries, and illustrates, in a graphic and forcible manner, the finest developments of our early and mediæval English art. The value of the series will be enhanced by an accompanying description in letter-press by Mr. W. de G. Birch."

**PREPARATION OF CHROME ALUM.**—Referring to this subject, *Les Mondes* says:—"The usual method is to dissolve bichromate of potash in sulphuric acid, and reduce by alcohol, or a current of sulphurous acid, and to avoid all elevations of temperature. A new method is to reduce by oxalic acid, and for 100 parts of chrome alum there are used 39 of concentrated sulphuric acid, 29.5 of bichromate of potash, and 38 parts of oxalic acid."

**A COOL CUSTOMER.**—The *South London Press* says:—"A stout old woman got vexed the other day because a photographer wouldn't let her fan herself while she had her picture taken."

## To Correspondents.

**D. REES.**—It is quite impossible to state how much nitrate of silver will be necessary to strengthen a bath after a given number of plates have been worked, because we cannot tell the proportion of bromides and iodides which the collodion contained, nor the number of ounces of collodion used, as an ounce of thin collodion will coat nearly twice the number of plates which can be coated with a thick collodion. As a rule, you will be quite safe if you keep the negative bath replenished in quantity with a forty-grain nitrate of silver solution.

**W. W.**—It is very difficult to say with certainty where you can obtain the powdery textureless collodion required for your purpose. If you made your own pyroxyline it would only be necessary to use weak acids at a very high temperature; but to those unaccustomed the process is a troublesome one. There are many good commercial collodions which do not possess that quality. Try Rouch's; we have had collodion of that quality from that establishment.

**N. S.**—Much depends on the actual condition of the india-rubber. Sometimes the hardness and want of elasticity may be remedied by placing in warm water for a time; but india-rubber is a perishable article, and by exposure to light and air it becomes oxidized, changing to a hard, friable resin, without any elasticity whatever. 2. Ponting's collodion was supposed to be at one time a simply iodized collodion containing iodide of cadmium only. Subsequently, we believe, a little bromide of cadmium was added. A suitable plain collodion—it must not be of too horny a structure—salted with one grain of bromide of cadmium and four grains of iodide of cadmium, will give you very similar results to Ponting's collodion. As a rule, it will be better after keeping a few months than when newly iodized. 3. We are not in the habit of making comments on such subjects, which could be of little service without very exhaustive trial. We have heard good accounts, but have made no trial. It is probably largely a copy of that you mention. 4. Mr. Joubert never disclosed any details of his carbon process. We used at one time to have a column of "Notes and Queries," which gradually got merged into our "Answers to Correspondents," as we found, in most cases, the answers devolved upon ourselves. We shall be glad, in deference to several suggestions, to revive the plan again. See a leader on the subject.

**CANTERBURY.**—It is doubtful whether the amount of gold obtained from the deposits of many toning baths would be sufficient to be worth sending to a refiner's; but you may utilize the deposit on the bottles by making it serve for toning purposes. Place hot water in the bottles, adding a few drops of nitric acid and a spoonful of chloride of lime, and shake well. The gold will be dissolved and after filtration the solution may be used for toning. 2. If a negative be found to require a very slight amount of intensifying after fixing, this may be effected by using a solution of iodine one grain, and iodide of potassium two grains, in water one ounce; or by application of a solution of hydrosulphate of ammonia, which will blacken the deposit. The strength of the latter is unimportant; but the best plan is to use it weak, and immerse the negative in a dish containing it.

**COLLODIO-BROMIDE.**—We have used methylated ether without disadvantage in almost every process, and we have no doubt whatever that it may be safely used in bromide emulsion processes; at any rate, we should have no hesitation in using it. 2. We should use, for diluting the emulsion which had grown thick, about two parts of ether to one part of alcohol. 3. It is difficult to advise. Emulsion with excess of bromide keeps best, whilst with excess of silver it is, we think, most sensitive, and most easy to obtain good negatives.

**PUZZLED.**—Much depends on the mode in which the negatives were produced, especially on the mode in which they were intensified. Some of the processes of intensifying after fixing leave the negative sensitive to light. Negatives which have, for instance, been intensified with bichloride of mercury, followed by iodine, often grow more intense at first after exposure to light, and sometimes they finally become very thin indeed. If you can inform us of the mode by which the negatives were intensified, we may possibly be able to give you some advice.

**C. A. OWEN.**—No. 3 on your list will answer your purpose best.

**A PRINTER.**—It is impossible to say with accuracy the cause of the yellow stains, as they might have been produced in several ways. A touch of nitrate of silver from any source whilst the prints contained hyposulphite, or a touch of hyposulphite when the prints contained silver, would cause such stains; acid of almost any kind, whilst the prints still contained hyposulphite, might cause such stains; imperfect fixation, arising from the use of old or weak hyposulphite solution, or from the prints being imperfectly immersed or stuck together during immersion, would cause such stains, and they would probably appear in such case for the first time during long washing. If they were washed in a dish which had been previously used for hypo solution, contact with the dish might cause the stains.

**G. K. W.**—There are various modes of producing transparencies for the lantern by printing on dry plates. Perhaps the simplest for an inexperienced hand will be the coffee process, which gives very good results. There is no especial secret as to the mode of producing those to which you refer; but the process is not easy to work, and requires much skill, experience, and care. We have several times published the details both in the *NEWS* and our *YEAR-BOOKS*. The transparencies in question are printed upon albumen. You will find details in our last *YEAR-BOOK*, page 130.

**PERPLEXED NOVICE.**—The fact that the marks on your negative always appear near the end of the plate at which the collodion is drained off suggests some imperfection either in the collodion or in the manipulation. Possibly your collodion is thick, or sets rapidly, giving an uneven film at that end of the plate where it flows last; or possibly you are not sufficiently quick and neat in coating the plate. Examine your film carefully, and note if there be some irregularity in the thickness at the point where the stain occurs.

Several Correspondents in our next.

The Photographic News, August 21, 1874.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

INVISIBLE PHOTOGRAPHS—PHOTOGRAPHY AT COOMASSIE—INDIA-RUBBER BANDS FOR DRY PLATES—PHOTOGRAPHY AND THE ORANGE RAYS.

*Invisible Photographs.*—Another seizure has been made in Paris of portraits of the Prince Imperial, but this time they were invisible ones; that is to say, they were not ordinary cartes-de-visite, but those magic pictures which were brought out as a novelty half-a-dozen years ago. It must require a vigilant police to seize things that are invisible, and a crafty politician to point out the baneful effects of such harmless toys, for these invisible photographs are nothing else. If they are of the character of the invisible photographs which were produced a few years ago, the pictures cannot last any time after they have been developed, as in a couple of days they are as yellow as a guinea; indeed, at best, they are not very striking pictures, and they are certainly never purchased in order to secure a lasting portrait, but only as a plaything. Our readers will doubtless remember how these invisible photographs are produced. An ordinary silver print is obtained, and, without toning or fixing, it is thrown into a strong solution of bichloride of mercury, which has the effect after a time of making every line and marking in the photograph disappear. The invisible picture is then dried thoroughly and placed in an envelope, ready for sale, there being contained in a second packet a sheet of thick bibulous paper which has been soaked in a saturated solution of hyposulphite of soda and dried. To make the image appear again, both these papers are dipped in water, and then placed in contact with one another, when the photograph will again appear almost as brilliantly as it was at first. Care must be taken that both papers are thoroughly dry when put away, otherwise, if packed in proximity to one another, development may take place too soon. It is the simplest thing in the world to prepare such photographs, and any one making the attempt will easily succeed. In this country, for some reason or other, invisible photographs are rarely to be seen at the toy shop, but there is no reason why they should not become as favourite playthings here as they are in Paris and other parts of the Continent. We repeat, they are produced with the greatest facility, and if a demand for them arose, their preparation ought to be a good source of profit to the photographer. It is quite possible, however—and, indeed, from the terms of the announcement, probable—that these invisible photographs were of a different character, and produced by a much less known process, to which we refer on another page.

*Photography at Coomassie.*—We hear that, after all, a photographer did push forward as far as Coomassie with his camera, in the person of an officer of one of the regiments that went to the front. Half-a-dozen small pictures of fair quality are said to be the results obtained; and as the negatives, we hear, have been placed in the hands of the Stereoscopic Company, we may hope soon to see impressions from them. It speaks something for the energy of an amateur to get his apparatus carried so far to the front under the acknowledged difficulties that existed in regard to transport; and we are sincerely glad to hear that what the Government failed in doing, a private individual succeeded in accomplishing at his own expense and trouble.

*India-Rubber Bands for Dry Plates.*—The packing of dry plates during a tour—whether they belong to an amateur who carries them in his portmanteau or knapsack, or to a professional photographer who has proper boxes for their reception—is always a knotty problem. Strips or triangles of glass are good things for separating the plates, if they can be firmly secured, and a flat triangle cap to fit over

the corners of the plates is as good an arrangement, pretty well, as can be suggested. But one wants something elastic to keep the plates together, and rubber rings are apparently the most suitable for the purpose. Unfortunately, india-rubber, when manufactured, is apt to contain sulphur, and it wants no chemist to point out that this substance, in minute quantities even, is sufficient to ruin delicate sensitive films. There may be pure rubber rings to be had, but it is very rarely met with, for the material in its pure state is so sticky and soft, after manipulation, as to be quite unserviceable for most purposes. The ordinary vulcanized rubber ring is of course pregnant with sulphur, which flies out in clouds every time the ring is stretched; and clean red rubber is only a trifle better, for it mostly contains sulphide of antimony in large quantities. In the latter case no free sulphur is thrown off in the atmosphere, but where the band comes into contact with the glass or film, there stains and patches inevitably occur upon the plates on development. Under these circumstances we would recommend that on no account should the band clasp the naked plates, but that one or two folds of paper should invariably be placed round first. The common white rubber bands ought never to be used, but the red antimony ones, unless it is really possible that rubber free from any deleterious admixture can be obtained. Sulphur, it should be borne in mind, is singularly prone to tarnish silver surfaces, and its action is much promoted when the metal is in the fine and delicate state of division we find it on our sensitive plates.

*Photography and the Orange Rays.*—The Vogel-Monckhoven controversy about the sensitiveness of bromide of silver to the orange rays of the spectrum is far from satisfactory, and Dr. Vogel's argument has recently been considerably strengthened by a statement of M. E. Becquerel, whose name is widely known as a scientific photographer and physicist. This gentleman affirms that M. Deshaies, of the *Conservatoire des Arts et Metiers*, has been able to reproduce some of the results obtained by Dr. Vogel. If this is the case, we no longer have the learned Berlin Professor standing alone as a champion for the actinic power of orange rays; but, apparently, we are not yet very near to the solution of the problem. Both Dr. Vogel and Dr. Monckhoven have promised to pursue their investigations further, and to publish the results.

AMERICAN CORRESPONDENCE.

THE PLUMBAGO PROCESS FOR REPRODUCING NEGATIVES—THE "GLACE" PROCESS.

*The Plumbago Process for Reproducing Negatives.*—A friend sends me the following details on this most valuable invention. He says:—

"I have been solicited by several photographers and others to give my experience in reproducing negatives by what is known by the 'powder' or 'graphite process;' and having carefully tested it for the past three months, I am prepared to endorse it, and, with your permission, will give the details of the process as I find best in my practice.

"The process is not new, being based upon a method invented by F. Joubert, and explained by him in a paper read to the Photographic Society on March 4th, 1862, an account of which will be found in the PHOTOGRAPHIC NEWS of March 14th, 1862, page 125.

"The first use of this process for the reproduction of negatives that has come to my notice was from Obernetter, of Munich, who gave a full description in the PHOTOGRAPHIC NEWS for March 27th, 1874. Since then a modification, by W. Woodbury, was published in the same journal for May 22nd.

"In recent experiments with these processes I find that with Obernetter's method our climate is too changeable to secure uniform success; and by Woodbury's method, though better adapted to our climate, there is too much uncertainty in transferring the negative after it is made; but where a reversed negative is required, Woodbury's method is all that can be desired; still I prefer a modification of Obernetter's, for the reason that the

resulting negative may be reversed or not at pleasure, and I have succeeded best with the following formula, viz. :—

Dextrine	...	...	...	...	4 grammes
Glucose...	...	...	...	...	4 "
Bichromate of potash	...	...	...	...	2 "
Water	...	...	...	...	100 "

"In very dry weather, and for very intense negatives in pure line, ten drops of glycerine may be added; but in warm weather, and for negatives full of half-tone, I prefer to leave it out entirely.

"This mixture is thoroughly dissolved by heat, and filtered, and a carefully cleaned glass plate is coated in the same manner as with collodion, except that it is allowed to stand a few seconds on the plate, so that all portions may be evenly coated; the surplus may now be poured back into the bottle, and the plate thoroughly drained on bibulous paper, and dried over a spirit lamp or a Bunsen burner, and then placed in contact with the negative to be reproduced when still warm, and exposed to light until the slightest trace of an image is visible, which will require about one minute in sunlight, or from two to five minutes in strong diffused light. The plate is then taken to a place where the light is not too strong, and brushed over with a camel-hair brush dipped in the finest graphite. The image will slowly develop, and may be strengthened by continued brushing to any desired intensity; but care should be taken not to make it too strong, as the graphite holds back the light more than silver. A negative, to print well, should be about as strong apparently as a good solar negative.

"Breathing on the negative should be avoided, except on pure line work where great intensity is required. On these breathing or blowing on weak parts may be an advantage, and such negatives can readily be made pure black and white. When the proper strength is attained, the plate must be coated with a thick plain collodion, and when well set immersed in a dish of water. One minute will be sufficient to remove all the yellow colour, when it should be dried; but if it should be required for ordinary silver printing it must be left in water until the film becomes detached, when it can be turned over with a camel-hair brush, and by holding the corners of the glass and film together, lifted both out together; drain, flow over with gum-water, and dry. Should there be dark spots in the negative, they can be avoided by using less glycerine, or keeping the plate slightly warmed during development. Transparent spots are caused by particles of dust or grease that repel the solution, making the coating thinner where they occur; if the solution is allowed to stand on the plate a few seconds before pouring off, these spots will not occur.

"My best results are with plates that require at least five minutes to develop, and the surface of the negative always retains a brilliant lustre, and the less glycerine used the better the lustre, but too little will prevent the development.

"It has been until recently impossible to obtain suitable graphite for this purpose; but I have to thank the American Graphite Company, 24, Cliff Street, New York, for the interest they have taken in the matter, by preparing the article in such a manner that I doubt whether there is any in the world that is better; and they have consented to put it up in any quantity to suit photographers and amateurs for experiments.

"Whenever a large number of pictures are required from one negative, this method has proved in my hands superior to any other, and I have no doubt but enlargements can be made as well if the exposure is made in a solar camera. This I have not tried yet, but intend to do so soon."

*The "Glaze" Process.*—For those who like plenty of "shine" on their pictures I add the following hints, from Mr. E. D. Dunsby, of Chicago :—

"Take a piece of clear glass, free from bubbles or scratches and clean by immersing in a solution of concentrated potash overnight. Wash thoroughly in clean water, and immerse for a few minutes in a mixture of nitric acid and water, one part of acid to three of water; let dry from the acid without washing. Now coat your plate with the following: plain collodion, one ounce; glycerine, one-half drachm, and let dry. Then take sheet gelatine and soak it in cold water until it is soft, then put it in a cream pitcher, or a wide-mouth bottle, and cover with water; dissolve the gelatine by heat, immerse your print in this warm gelatine, and lay face downward on the collodionized plate, carefully pressing out all air-bubbles; now cement with gelatine a piece of thin Bristol board, previously dampened to make it pliable, to the back of your print; let dry thoroughly, and loosen the edges with a

knife-blade, by running around the glass between the print and glass, when the whole thing will leave the glass with a very superior polish; it is now ready for pressing in Ormsby's cameo press, the simplest, most practical, and cheapest cameo press ever

invented. Any carpenter will make one for about three dollars. The press and process are free for the use of the fraternity. This process is superior to any. Where rubber is used in the collodion, they will never crack in pressing, and where the rubber gives less polish than collodion alone, the addition of glycerine gives an extra polish. I enclose you a photograph of my press. It is made of maple wood, three-quarter inches thick. The raised centre for moulding is glued on. It is so simple that the photograph explains it. The top and bottom are hinged together. My press and process have the endorsement of the Chicago Photographic Society."

EDWARD L. WILSON.

#### GERMAN CORRESPONDENCE.

THE DULL SEASON—AMERICANS IN GERMANY—RETOUCHERS AND RETOUCHING—OBERNETTER'S METHOD OF MAKING TRANSPARENT POSITIVES—VENUS EXPEDITION—PHOTOGRAPHIC RESEARCHES WITH THE SPECTRUM.

BY DR. H. VOGEL.

WE are now in the midst of the dull season. In spite of the cold summer and incessant rainy weather, the metropolis gradually gets empty. The can-get-aways go to the watering-places or to the mountains; and gradually our galleries assume a deserted look; only now and then a timid stranger puts in an appearance with the red Baedecker or the brown Murray in his hand. Amongst our visitors are many Yankees, who ask for a ferrotype, or even a porcelain picture, neither of which are made here. At this writing a caravan of forty ladies is staying in Berlin, and all of them have been immortalized in the shape of Berlin cards.

"Do you consider the Berlin pictures superior to the American ones?" I asked a young American lady who had her picture taken. "Oh no," she answered, "I consider the American ones better, and only get a picture here so as to show my countrymen how far we are ahead in photography." Such patriotism is very acceptable. I have always met it in the American ladies. "Do you know Mr. Roeder, of Chicago?" inquired another lady. "Yes, Madam, very well," was my reply. "Is he not the first photographer in the world?" exclaimed the lady. "No, that is Mr. Scholten, of St. Louis," replied her friend, a resident of St. Louis. You see that the American photographers are very well defended here, and I would propose that at a future international exhibition (1885, in

Berlin ???), America will send female jurors only—young and handsome preferable.

Although business is very dull, our society has not been idle; the summer meetings were even better attended than the winter ones; and recently a very animated discussion was devoted to the negative retouch, but this time the discussion did not turn on technical matters, but on the retoucher himself. The cause was the fate of several retouchers, who, relying on their art, had opened galleries for themselves, and, in spite of their skill as retouchers, had failed of success, because their manner did not please the public, or they did not possess the ability to pose and light a person rapidly and properly, or because they lacked business ability. These facts have demonstrated that to carry on a photographic business more is necessary than merely technical skill. On the other hand, it was maintained that the proprietors of many galleries are good business men, and know how to make money, but do not possess any knowledge of art, and expect of their retouchers impossibilities. It is certain that the photographic negative retouch does not exercise a beneficial influence on the photographer. Fritz Luckhardt, in Vienna, states that he had a first-class artist as retoucher, who, in the beginning, made excellent work, but afterwards displayed a tendency to make everything smooth, and even to remove the characteristic lines. This is not brought about by want of taste or knowledge of art, but is due to the fact that the eye becomes dulled by use, and the opinion is general that no one can stand it longer than ten years. Mr. Prumm employs his retouchers for half a day on the negative, and the other half on the positive, and states this change enables his workers to last much longer. Lately a reaction against excessive retouching has set in. A number of photographs from 1862 were exhibited, at which time retouch was unknown, and the opinion was generally expressed that, artistically, and in point of reproducing the characteristic features, they were fully equal to the productions of the present day. The retouch is now curtailed by many, and I have particularly to mention an artist by the name of Technor, who makes excellent portraits, which he retouches only with a few lead pencil lines. We have learned also that no artificial light effects are necessary in order to produce a characteristic portrait. Side-light pictures, Rembrandts, and other tricks, have long been laid aside.

Another important chapter which is discussed a good deal is the reproduction of negatives. The labours of Obernetter in this branch cannot be over-estimated. Of course, not everybody will obtain good results with his process; but the matter is of such great importance that no one should give it up if the first attempts are unsuccessful, as perfection can only be acquired by practice.

Obernetter has recently published a process of making a positive from a negative by means of the dust process. This process is not as important as the other. The making of negatives from a positive may also be made, with little trouble, by the collodion process. Besides, the time of making positives by this process is, according to Obernetter's statement, longer. The method itself is not new, and was originated by Poitevin. The latter took a solution of chloride of iron and tartaric acid, and coated with it a plate of ground-glass, and, when dry, exposed it to light. The light reduces the sesquichloride to a chloride; the latter, when exposed to the air, attracts moisture, and pigment powder dusted over it adheres to the same. Obernetter recommends for this process the following mixture:—

Citrate of the oxide of iron	...	10	grammes
Citric acid	...	5	"
Sesquichloride of iron, concentrated solution	...	2	"
Water	...	100	"

The citrate of iron is finely pulverized, and is placed, with

the other ingredients, in a flask, and heated to boiling, and left to stand until the citrate of iron has dissolved. When cold, the solution is filtered. The plates which are prepared with this solution are slightly warmed, coated, and dried in a drying oven. In from five to ten minutes the plate is dry, and placed, while still warm, in the printing-frame, on the negative, and exposed in the sun for from eight to ten minutes, in the shade for one hour. After exposure, we breathe upon the plate, when a feeble image will appear. By means of a brush, plumbago or red oxide of iron is dusted over the plate. Obernetter states that it is easier to dust such a plate than one prepared with chromate of potash. When the plate has been dusted, it is coated with plain collodion, placed in water for four minutes, when the film is removed, and transferred to another surface. If the picture is to remain on the original surface, a three-fold diluted solution of iron is used in the preparation of the plate, and the plate is coated with castor oil collodion, and left to dry. The picture can be varnished.

The expeditions for the observation of the transit of Venus are starting. On the 22nd, one of our parties started, in the man-of-war *Elizabeth*, for Kerguelen Island, and will meet on this uninhabited group of islands the English expedition and your countrymen, and lead, for at least eight weeks, a scientific Robinson Crusoe life. In two weeks, the second expedition starts for Auckland Island, south of New Zealand. This one Krem, of Dresden, accompanies, with his son, as photographer; and four weeks later the expedition for China departs, with which I intended to sail, but, unfortunately, my obligations here make it impossible for me to be absent seven and a-half months. I regret that I will not be able to give to your readers photographic reports of India and China, but hope to find here sufficient material.

My credulity is somewhat shaken when I read that not only your honoured townsman Mr. Carey Lea, but also my honoured colleague Monekhoven, enter the field against my discovery of the action of yellow and red rays on bromide of silver. He has repeated my experiments, not with coloured glasses, but with the true, real, genuine spectrum, and has not obtained my results. Yes, and he asserts that in the Ecole Normal in Paris, and in Bunsen's celebrated laboratory in Heidelberg, my experiments have been repeated without success. An anonymous writer in the *British Journal* speaks in the following manner:—"Messrs. Carey Lea, Spiller, and others, have given the final *coup de grace* to this notion of Dr. Vogel, and his fine theory of a prolongation of the action of the more refrangible rays of the spectrum must henceforth be relegated to the limbo of photographic abortions." First executed, next banished (relegated), and fortunately I have suffered both proceedings from the distance without any inconvenience or damage, and have even, as an executed exile, the impudence to continue my experiments. If I had only tried two or three plates with the spectrum, a doubt might be possible; but when two to three hundred experiments have been made with absolutely the same result, there must be something more in it than a photographic abortion. Photographic spectral experiments are rather difficult to make. They cannot be repeated with coloured glasses, for these colours are impure, and experiments with impure colours belong to the same category as a chemist who wants to make a chemical analysis with impure chemicals. The objection that the spectral colours are not always pure, either, is not valid, for the same can be said of the "pure" reagents of the chemist. Monekhoven has experimented with pure spectral colours, and did not obtain my results. The explanation is easily found. Monekhoven's spectroscope had a slit seven and a-half times smaller than the slit of my instrument, hence seven and a-half times less light entered his instrument than mine. Further, he elongated his spectroscope to forty centimetres—that is, he made it seven

times longer than mine—and the consequence was that his instrument was fifty times more feeble in light than mine. Now with my instrument of great intensity of light, I had to expose for three minutes in order to obtain an impression in yellow. Monckhoven would have obtained the same result if he had exposed for three by fifty minutes, or one hundred and fifty minutes. Instead of that, he states that he exposed for two minutes only. Monckhoven is in the position of a photographer who wants to try a very sensitive instantaneous collodion, and employs for the purpose a slow-working landscape lens of feeble light. I have to mention still another mistake. Dr. Monckhoven probably coloured his plates too highly. An intense colour is not beneficial, but objectionable. Each particle of bromide of silver is surrounded by an envelope of coloured collodion. If the colour is too intense, the light is weakened too much by being absorbed by the envelope, and can, therefore, not act with sufficient energy on the bromide of silver. A weak colouring, which can only be established by experiment, is the only way to success.

#### PHOTOGRAPHING AN EXHIBITION.

A PAPER recently read before the Vienna Society, by Mr. Oscar Kramer, gives a graphic account of the troubles and disasters of the Association of Vienna photographers who undertook the contract for photographing in the exhibition, an undertaking for success in which, in various English International Exhibitions, Mr. England has acquired a reputation quite equal to that he had already secured for his stereoscopic and other landscape work. To commence with, the "World's Exhibition" at Vienna seems to have been a failure throughout, and, so far as the task of photographing its contents is concerned, that failure seems to have deepened to disaster. We make a few extracts which may be useful as beacons, if not as guides, to photographers who may undertake similar work. After some preliminary statements, Herr Kramer says:—

"In my address of last year, I described how the four ateliers formed the association and established themselves in the exhibition grounds, and called able assistance in from other places for special branches. The working corps for taking negatives numbered fifty men, and the supply of instruments consisted of more than one hundred pieces. This well organized and supplied body entered hopefully and energetically upon the campaign, prepared, indeed, to find it one of hard work, but little expecting that it would soon partly resolve itself into a struggle for their rights. Difficulties, some unavoidable, some invented for the occasion, arose in all quarters, involving the association in such perplexity as to demand for the successful fulfilment of its mission the greatest zeal and self-sacrifice on the part of all its members.

"Our first great enemy, one against which the photographer stands powerless, was the bad weather, which lasted during the greater part of May and the whole of June (I need only remind you of the opening day, in anticipation of which eight scaffoldings had been erected, four on the rotunda, and four before the southern portal, capable altogether of taking sixteen groups, and all of them useless when the time came). That rainy epoch was marked by countless spoiled impressions and useless negatives, and the infliction of a general catarrh on the photographers. But besides the unfriendly Jupiter Pluvius, there was another god, upon whose favour and assistance the association confidently relied, but who often left it badly in the lurch. This was his Excellency the General Director, Baron Schwarz. This personage, on my frequent pressing visits to him—visits which involved for me the loss of hours and days—always evinced the utmost courtesy and readiness to enter into my well-meant representations and proposals; but, amid the press of other weighty matters, unhappily too often forgot to give the necessary orders for executing them.

"Nothing but the splendid promises of the General Direction, and their assurances secured by contract, would have induced the Messrs. Frankenstein and Co., Klösz, Löwy, and myself to undertake the hard and delicate task, which no one else had dared to venture upon, in view of the losses which those suffered who undertook the photographic work at the last exhibition at Paris. These promises and obligations have in many important particulars remained unfulfilled. By the provisions of our contract with the General Direction, we were to have in the exhibition buildings an

office, and the necessary number of dark rooms for our photographic operations. We received neither the one nor the other, and were at last forced to erect a building for our laboratories and offices, at a cost of 15,000 florins, and also to construct a number of dark rooms on wheels. Our supply of water had been secured by contract; but we were obliged to negotiate for more than four weeks before the pipes were actually laid. Among other things the General Director promised to aid us with considerable orders for photographs, and we made the pictures of the buildings in process of erection, relying on this promise, for it is easily seen that there is no profit in pictures of that character, they being of interest only to a small circle of specialists. This promise also remained unfulfilled. Indeed, an order given in the beginning was afterwards countermanded, and most of the pictures returned. Have thus been deprived of the protection freely and solemnly promised us, we were further exposed to many vexatious hindrances by over-zealous officers. When, for instance, the General Direction posted up placards forbidding the reproduction of articles in the exhibition by drawings or copies, all operations of the association, which had been created and commissioned specially for the exhibition, came immediately to a standstill, for the General Direction forgot to exempt us from the decree; and so for weeks and months our operators were driven off by the officers, hindered in the performance of their duty, and even several times arrested, in spite of certificates signed by his Excellency himself, in spite of special permits, in spite of our petitions and protests. In one case our apparatus was confiscated in the Italian department, and we were obliged to take special steps, and lose much time, to get it back again.

"It was a great hindrance to us, during the first months, that the greater part of the arrangements for the exhibition were not yet completed. The unpacking of articles by exhibitors, operations of decorators and work-people, a medley of boxes, carts, unfinished gardens, planks nailed up to prevent passage, unpainted pedestals not yet surmounted by statues—all these either prevented us from taking pictures, or made it necessary to repeat them afterwards. We had to overcome countless difficulties, some caused by the crowded space, some by necessary and unnecessary safety regulations. Our people were not allowed to begin work in the interior of the exhibition buildings before 7 a.m., and by 6 or 10 a.m. it was generally no longer possible to take pictures, on account of the assembling public. In these rooms no photographs whatever requiring long exposure could be made, principally on account of the unsteady floor; so that for several hours the gallery was as good as closed to us. Our Mr. Laury had brought with him from Paris three ingeniously contrived pieces of apparatus for dry plates, expecting to set them up in the galleries in the evening, and expose them there until morning. They could not, however, be used a single time, because the floor vibrated under the tread of the patrol and washer-women, and rendered it impossible to get a clear, sharp, well-finished negative. On account of the very bad arrangement of the articles exhibited, the perspectives of nearly all the galleries, otherwise so imposing, were spoiled, and very few lofty, firm stand-points were obtainable from which good interior views could be taken. Besides this, the reflex lights playing about objects rendered the hope of getting a good negative illusory, and it was often necessary to spend time and money in arranging tapestry hangings for regulating the light before we could accomplish our object.

"Our operations in the Hall of Art were attended with similar calamities. The photographers were strictly forbidden to move the pictures from their places, and, as a consequence, certain paintings could not be photographed at all during the exhibition. It also required much time and pains to get permission from the artists themselves to photograph their pictures. Most of them never answered our repeated requests. Replies from some were received in January and February of this year. This passiveness or reluctance of the artists is much to be regretted, since it causes a serious gap in our collection of pictures. The Italian sculptors were, however, very courteous, and we therefore have reproductions of nearly all their works, which will soon secure for them a large circulation and great popularity.

"We also met with many difficulties from the exhibitors themselves. Here was one who wanted nothing but his own stall included in his picture—his neighbours meanwhile refusing to have their articles shut off from view. There was another, not content to shine in his own feathers, but wishing to don those of his neighbour too—a thing which the latter would by no means consent to. And so the photographer had not seldom to play the part of mediator, or get involved in a quarrel with two or three parties, while executing a single order.

"While our operators were thus perplexed and hindered, and put to needless expense by a hundred vexatious circumstances, other things combined to reduce very materially the receipts of the association. I need make no reference to our delusive hopes of a large attendance at the exhibition. In this respect every one was completely deceived, from the projectors of it to the needy citizen who with his family took up his quarters in the kitchen, that he might let his rooms to some "rich Californian." Although the slender attendance cut down the sale of our photographs, there was still another important circumstance, which would have made it impossible to dispose of a large quantity, even had the attendance been very large. According to contract, all sales of photographs of the exhibition were to be made by the so-called Exhibition Book Association. This establishment, besides coming into the field at too late a day, was situated in an out-of-the-way place, where few looked for it, and nobody found it. The pictures went off so slowly that we should not have been able to cover the expenses of a single month by our sales during the whole period of the exhibition. At length, in July, after endless running to and fro and loss of time, we obtained permission from the General Direction to set up some tables in the exhibition buildings, and engage saleswomen. Thus nearly everything which was to have been provided for us by the General Direction, in accordance with our contract with that body, we were finally obliged to procure at our own cost, in spite of the fact that our license had been rated at the large sum of 20,000 florins.

"Such is the sad story of the Association of Photographers for the World's Exhibition of 1873."

The following negatives were taken:—

Folio size,	{ Negatives	81	
	{ Duplicates	11	92 negatives
Half Folio size	{ Negatives	84	
	{ Duplicates	7	91 "
Quarter Folio size	{ Negatives	1358	
	{ Duplicates	1386	2744 "
Cabinet size	{ Negatives	1694	
	{ Duplicates	1798	3492 "
Stereo. size	{ Negatives	506	
	{ Duplicates	596	1102 "
Cartes-de-Visite	{ Negatives	2571	
	{ Duplicates	4276	6847 "
Giving a total of			14,368 "

without reckoning several hundred negatives made by Mr. Schnäbeli at the Animal Exhibition, and a large number of spoiled plates. The whole cost of a complete collection of the photographs, reckoned at the usual retail prices, would be about 5,000 florins."

PRINTING PHOTOGRAPHS IN GREASY INK WITHOUT A PRESS.\*

You commence by obtaining in the first place, by means of the carbon process, an impression upon a glass plate (its provisional support), which is covered with a varnish made from a solution of 2 to 3 grammes of good gum dammar in 100 cubic centimetres of purified benzole.

The print is then surrounded by a margin, or framework, by means of a mastic of some kind, while you prepare in a water bath the undermentioned solution:—

Gelatine	...	...	...	1 part
Gum arabic	...	...	...	1 "
Glycerine	...	...	...	2 parts

Dissolved in as little water as possible.

This mixture is poured in a tepid state upon the carbon print, which is slightly warmed, so as to form a thick film over the image. When the gelatine compound has set sufficiently, it is detached from the glass. The mass of gelatine, in which is incorporated the carbon print, when reversed and applied to some plain surface, is then ready to serve as a printing-block.

The image, formed of gelatine, which the light has rendered insoluble, takes the printing ink, while the ground of the image, formed of gelatine in its natural state, absorbing moisture easily, repels it; these two effects, opposed to one another, are produced in proportion as the light has acted upon the carbon tissue.

When you desire to take off impressions from the film,

it is inked with ordinary lithographic ink of a hard character, moistened with a little olive oil, oil of turpentine, or indeed, any oil with the exception of boiled oil.

To ink in, use is made by preference of a roller of ground glass (a tube of large diameter). The ordinary lithographic roller employed for stone adheres too firmly to the surface, and has a tendency to mutilate the image.

A little ink is applied to the roller in patches, and then, to get the same equally spread over the surface, the roller is worked to and fro over an elastic body. A gelatine surface similar to that carrying the image is just suited to the purpose.

When the roller is uniformly covered with ink, without being too much charged, it is passed over the carbon print until the latter appears to be sufficiently inked. If need be, the superfluous ink may be removed with a damp rag, and a linen cloth moistened in water will take away any dirtiness that may be seen upon the plate.

If the ink employed is too hard, it will be found to adhere only to the deep shadows; if you wish it to adhere to the half tones, it must be thinned a little. This circumstance may be made use of to get more depth out of the shadows, and also to obtain from one plate prints of various tints. You proceed as follows:—

Two or three inks of different thicknesses, and, if you like, of different colours, are prepared. You commence by inking the print with the thickest, which only adheres to the deep shadows, and then proceed to apply one more dilute; this does not act upon the first layer of ink, but attaches itself to the half-tones, and to these only. In this way impressions may be obtained upon a coloured ground.

To produce your impressions, you apply a supple sheet of paper—which may be glazed or covered with uncoagulated albumen—to the inked surface, and press it upon the film by means of a rubber squeegee, or scraper, or by the aid of a flannel roller. When sufficient pressure has been exerted, the sheet, carrying upon it the impression, is gently raised, and separated from the film. You then proceed to pulling off a second print, inking up the image with care; but before doing this the printing block should be gently wiped with a damp rag.

To obtain prints with a margin so that they need not afterwards be mounted, a paper mask is made with an opening corresponding to the size of the print, and this mask is interposed between the inked block and the sheet of paper to be printed upon.

The cliché to be employed must be a reversed negative—that is to say, a negative which has been obtained in the camera through the glass. If such a negative is not forthcoming, then the development of the carbon print is conducted upon stearine paper prepared by placing a sheet of albumenized paper upon a bath made up of—

Alcohol, ordinary	...	...	100 cub. cents.
Stearine	...	...	15 grammes
Resin, ordinary	...	...	2 "

The resin is dissolved in a warm state, cut up into fragments in the alcohol, and the resin is added after solution.

The carbon print developed upon this provisional support is then transferred to a plate glass, and covered with gum dammar varnish.

The facility with which, by this process, it is possible to print upon rounded objects, such as bottles, vases, &c., allows you to employ it for ornamentation, vitrifiable pigments being used for inking the film.

The principal advantages that this method of printing in greasy ink enjoys for producing photographic positives are:

1. The absence of any complicated apparatus, so that it may be employed by any amateur.
2. The formation of the printing block upon a gelatine surface, necessarily very uniform and exempt from pressure, without having recourse to any method of preparation.
3. The large number of prints that a prepared film will furnish in this way, the inking and pulling off of pictures having little destructive effect upon the block.

### INVISIBLE PHOTOGRAPHS.

Most photographers are familiar with the invisible photographs which became popular as toys a few years ago, the invisible image being formed by treating a silver print with bichloride of mercury, the mode of rendering it visible again consisting simply in bringing it into contact with hyposulphite of soda. To this method we briefly refer in another page. The seizure, in Paris, of invisible photographs of the Prince Imperial revives the subject in public interest; but it is probable, from the terms of the paragraph announcing the seizure, that the invisible portraits were not of the character of the toys referred to. In the first place, immersion in water simply would not render visible the images produced by the action of the mercury salt; and, in the next place, such an image, once made visible, cannot be easily again rendered invisible. It is manifest that the especial charm about an interdicted print would be the possibility of making it visible and invisible at will. There is, however, a form of invisible photograph which can be rendered visible in a few seconds, and in a few seconds more invisible; and as the method, although very simple, is comparatively little known, a few words on the method of producing them may interest our readers.

We may premise that, although the process is simple and obvious enough, we do not remember to have seen it described, nor to have met with other examples than those we have ourselves produced, and one forwarded to us some years ago by a correspondent, without any details as to the mode of production. This print—the first of the kind we had seen—appeared to be a stout piece of plain paper, with instructions written on the margin to float it on water. This done, in a second or two an image appeared on the plain paper, but it required an examination by transmitted light to appreciate it. So examined, it presented a very good transparency, the paper having quickly absorbed water, and become quite transparent in the lights, whilst the shadows of the picture were formed by the paper being non-absorbent, and remaining opaque in the dark parts. Many of our readers will at once appreciate the principle upon which the picture was produced, and upon which we proceeded to produce something similar. A variety of experiments were tried. Ordinary albumenized paper was floated upon a twenty-grain solution of bichromate of ammonia, dried, and exposed under a negative, and then soaked for some hours in warm water. The result was only a partial success, the lights being insufficiently transparent, and the shadows insufficiently opaque. Stout printing paper, and Turner's

calotype paper, gave pretty good results, but still not quite perfect. They required very long soaking in warm water, to which a little carbonate of soda was added, to dissolve and remove all the sizing of the paper, so as to render the lights absorbent enough to become readily transparent.

But the best result was obtained by commencing with bibulous paper, and adding to it all that was required to form an image. We used a stout bibulous paper of the character of plate paper. This was floated for a few minutes upon a weak solution of gelatine. We can only estimate the strength; but it was probably about a ten-grain solution. This, after drying, was immersed for a few seconds in a twenty-grain solution of bichromate of ammonia and dried (in the dark, of course). The paper so prepared was exposed under a vigorous negative for about the same time we should expose a silver print, a well-marked brown image on the yellow ground being obtained. This was washed in a few changes of warm water, and then left to soak for a few hours, after which it was dried. After drying it is only necessary to float the print for a few seconds in water, and render the image visible. The gelatine has been rendered insoluble and non-absorbent wherever light has acted upon it sufficiently, and therefore it remains comparatively opaque when brought into contact with moisture. But in the lights, where the gelatine has been protected by the dense parts of the negative, it maintains its solubility, and is readily removed, as well as all traces of the unaltered bichromate, by the washings in warm water, and the bibulous paper in these parts retains its ready capacity of absorbing water, becoming transparent when wet.

The first conclusion of the experimentalist familiar with the ordinary results of printing with chromates and organic matter will be, that from the operations described an invisible image, strictly speaking, would not result. The first action of light upon a surface of gelatine and a bichromate is to produce a brown tint, the result of the formation of chromate of chromium. This, when submitted to the action of water, is decomposed, a pale green image of sesqui-oxide of chromium being left. To remove this tint requires long soaking, and perhaps a little aid from the action of a dilute alkali. Repeated washings with warm water, to one or two of which, as we have suggested, a little carbonate of soda has been added, gradually remove the green tint, leaving a colourless image of gelatine, only rendered visible by its insolubility and opacity upon a ground of readily absorbent paper, which becomes transparent at once on being placed in water.

Besides the interest attaching to a print which can be made visible or invisible at will, a variety of curious applications for such a process will readily occur to readers, which we need not here indicate.

### PRELIMINARY COATINGS OF ALBUMEN.

In the hands of the majority of photographers the use of albumen as a substratum in the wet collodion process has of late years proved a complete success; but, oddly enough, in the hands of a few—and these experienced and capable men—it has proved beyond question a failure. It is somewhat important to ascertain the cause for this; because, where the plan succeeds, it is full of advantages. It saves half the trouble and all the anxiety of securing clean plates; it tends to the production of a finer negative, and it removes all risk of the film splitting from the glass. Where, however, it is a failure, it is fatal: it destroys the photographer's sheet anchor, a nitrate bath in good condition.

A communication from an experienced and capable amateur photographer on another page describes the phase of failure after repeated trial. Unfortunately a point of some importance in the statement of the difficulty is not included, namely, the strength of the albumen solu-

tion, and its mode of preparation. Much, if not all, depends on the albumen solution used. When, many years ago, albumen was first used as a preliminary coating, it was customary to use white of egg alone, or very slightly diluted, and the result was almost invariably a disordered bath and foggy negatives in a very short time. Mr. McNab, one of the earliest portraitists who employed the albumen substratum in his regular wet plate work for portraiture, found it necessary to coagulate the albumen film, which he effected by application of a solution of sulphate of iron, and this he found effectual in preventing injury to the bath. Various other portraitists gradually followed Mr. McNab's example when we published his experience twelve years ago. Mr. Henderson, of Perth, was another of the early workers with albumen as a substratum, and he also in early years was in the habit of coagulating the albumen. After trying various formulæ, originally using equal parts of white of egg and water, with a little ammonia, he finally adopted a very much more dilute preparation, using the albumen of one egg, twenty ounces of water, and one ounce of spirits of wine. With his plates prepared in this way, he informs us, he has for many years experienced not only total immunity from trouble, but better results in every way than he could obtain without the aid of the preliminary albumen coating. Some able and successful men work with an albumen solution containing forty ounces of water to the white of one egg, and in one case we have heard of the use of one hundred ounces of water to the white of one egg, giving a solution so attenuated that it is difficult to believe that it would leave an appreciable film on the glass.

The tendency of the evidence on the subject that has come under our attention from time to time has led us to the conclusion that danger to the bath arises from two causes: the use of the solution unnecessarily strong, and allowing the albumen to run over the edges of the plate. The first is easily avoided by using the most dilute preparation which has been found efficient, say the white of one egg to a quart of water; and the second is avoided by the use of a Blanchard brush for applying the solution, which will permit the coating to be brought within a quarter of an inch of the edge of the plate without risk of any running over the edges, so as to come into direct contact with the nitrate bath. From the experience and care of our correspondent, we can scarcely suppose that neglect in relation to either of these sources of error can have been the cause of his failure, and we shall be glad if any of our correspondents can throw additional light on the question.

THE PRACTICAL PRINTER IN AMERICA.

IV.

MODES OF RECTIFYING THE PRINTING BATH.

A PRINTING bath, the proper strength of which is maintained by the addition of one ounce of nitrate of silver to each quire of paper sensitized, and sufficient water to maintain the normal quantity of solution, will rarely require much doctoring, especially if the suggestion given in a previous chapter, of keeping a little carbonate of silver in the bottle, be adopted. Mr. Hearn, however, gives a resumé of the various modes available for removing discolouration. He says:—

“The bath, after it has been used for some time, discolours, owing to the albumen of the paper being left in it after floating, or dirt and other impurities having got into it through accident, leaving the dish uncovered when the bath was not in use, imperfect filtrations, and chemical matter which was impure, and by age having showed itself.

“*Permanganate of Potash.*—When the bath is only a little discoloured, and is a new one, this solution will for awhile answer capially:—

Permanganate of potash...	...	60 grains
Pure water	...	6 ounces.

Add about half a dozen drops, and stir the solution well with a clean glass rod. At first the bath will turn a dark rose colour, and it will then considerably lighten, and if it does not stay so, but utterly disappears, then add a few drops more until a temporary colour appears. Now place the bath out in strong sunlight for half an hour, and after it has thoroughly cleared, and the rose colour has disappeared, the organic matter can, in a great measure, be filtered out.

“Mr. Elbert Anderson, in his book, ‘The Skylight and the Dark Room,’ accounts for the action of this permanganate as follows:—‘As soon as the permanganate comes in contact with the bath the organic matter becomes oxidized, and permanganic acid is liberated, forming permanganate of silver, which remains in the bath, and is precipitated to the bottom in dark, brownish-black flakes, whilst the permanganate itself is converted into peroxide of manganese. As soon as the solution is perfectly clear, most of the organic matter will be filtered out. Thus the permanganate precipitates most of the organic matter without the least injury to the bath.’

“*Kaolin.*—This is often used for clearing up the printing bath. A little of this powder is placed in the bottle containing the discoloured bath, and the solution thoroughly stirred with a glass rod, and then allowed to settle for the space of a few minutes. Filter the decanted solution through cotton, and at night pour the bath again into the bottle containing the kaolin. Thus the same kaolin can be used for a great number of times.

“Mr. F. A. Bridge, in the YEAR-BOOK for 1873, recommends, for those printers who use the kaolin, a simple apparatus described as follows:—‘Take a large wide-mouthed bottle (depending upon the quantity of solution you have in use), fit a cork to it, and bore three holes in it, one large enough to admit the point of a funnel, going well through the other side, and the other two large enough for a piece of ordinary glass tube. Bend a piece of tube in the form of a syphon, let one end reach to within about an inch of the bottom of the bottle, and let the other end be a few inches longer; break it off below the turn in the longest side, and join it together again by means of a piece of india-rubber tubing about two inches long; put another piece of glass tube (slightly bent for convenience sake) just through the cork, and the thing is made. Put some kaolin in the bottle, and after using the solution return it to the bottle through the funnel over-night, and shake it; it will be quite clear by the morning. When again required for use, you have only to cover the top of the funnel, put the long end of the syphon in the dish, blow gently down the short tube, and the syphon immediately commences to act, and continues to do so while there is any solution to supply it; and if care is taken to stop it before the top of the solution reaches the level of the syphon tube (which may be done at any time by pressing the piece of india-rubber tube), no serum will ever get into the dish.’

“*Gum Camphor Solution.*—When the bath is very much discoloured, this rectifier is most generally used. It is made as follows:—

Gum camphor	...	...	1 ounce
Alcohol, 95 per cent.	...	...	6 ounces.

Add about four drachms of this solution to the discoloured bath, and shake well. Probably the frothiness which is at first formed will disappear, and then it will be necessary to add another equal quantity, if not more; shake well, and then allow the bottle to stand for a few minutes without being shaken. Filter the solution through paper, and the albumen, which, united with the camphor, will be left in the filter, and the bath will be very clear.

“*Boiling down the Solution.*—About once a month or so the printing bath should be boiled down about two-thirds. It is first made very alkaline with aqua ammonia, and is then placed in an evaporating dish over a small gas stove,

and a small jet of gas turned on. When it has boiled down two-thirds, turn off the gas, and permit the solution to cool gradually, leaving the dish on the stove in the meantime. When cool, filter through paper, and test the strength of the silver by means of Pile's test tube\* and solution. Add water to reduce the bath to that strength which is best for the paper, negatives, &c. Then add the other nitrates (or whatever other chemicals that might have been used in the making of the bath in the first place) to the bath, see to the alkalinity, filter, and the bath will be ready for use.

**"Fusing the Bath.**—Place the bath in a suitable size evaporating dish, and boil down to dryness at a gentle

heat. Scrape the silver which has adhered to the sides of the dish down to the bottom, and stir the solution with a glass rod until all the bubbling has ceased. Now turn off the gas jet, and stir the mass constantly with a glass rod until it has cooled, and then the mass will be broken up, which is a more desirable state to have it in. In an hour or so after you have left off stirring it, you can dilute the

strength of the fused mass by the addition of pure water. Reduce to the proper strength for the printing bath, and then filter the solution. The organic matter will be left in the filter. Now make up your bath as has before been advised, and then it is ready for use.

**"Sunning the Bath.**—The bath is made alkaline and placed out in the sunlight, for the purpose of throwing down the organic matter in it.

"The bath is very much improved by sunning, and it should always be placed out in the light when not in use.

"To prevent evaporation, keep the bottle tightly closed.

**"Filtering the Bath.**—This can be done either by means of common filtering-paper, or through cotton.

"Good filtering-paper can be obtained from almost any stockdealer, of various sizes, all prepared for immediate use. Sometimes the filtering-paper is rendered useless on account of there being traces of hyposulphite of soda in it; but this is very seldom the case. If you have filtering-paper of which you are suspicious, you can test it by the following simple method:—Take a sheet of the suspected lot of paper, and place it in a small and perfectly clean evaporating dish in which there has been placed a small quantity of warm distilled water—say five ounces. Cover the dish over with a glass, and let the paper soak for a few hours, and then boil the water, still with the paper in it, for the space of half an hour. Take a clean test-tube, and squeeze about an ounce of the water from the wet paper into it. This should be done with perfectly clean hands. Now dissolve about five grains of permanganate of potash in about an ounce of distilled water, and then add ten grains of bicarbonate of soda to it. When this solution is thoroughly dissolved and mixed, then let fall about three drops of it into the test-tube containing the water squeezed from the filtering-paper. If there is a trace of the hyposulphite in the water, the liquid in the test-tube will turn a more or less greenish tint, according to the quantity of the soda there may be in the solution. Look sharp. If there be no hyposulphite there, the rich colour of the test solution will not be lost, although its deepness may be weakened. When the latter is the case, the filtering-paper does not have anything in its composition that will be at all injurious to the bath when filtered through it.

"When preparing to filter your bath solution through paper, the paper should be folded in six or eight places, so as to permit the air from the bottle to escape between the folds of the paper, and thus allowing the solution to filter quicker. In folding, be careful that you do not

break the centre of the sheet of filtering-paper, at which the folds meet.

"The paper should be placed in the funnel, and when the solution is poured into it to be filtered, it should be poured at the side of it, slowly at first, so that the weight of the solution will not be likely to break the filter.

"When it is desired to filter the bath through cotton, the cotton should be wet thoroughly with good common alcohol, and thrown into the funnel. Now pour the solution in, and filter the bath.

"If it filters too quickly—i. e., imperfectly—then press the cotton down further in the neck of the funnel; if too slowly, then place the glass rod in the centre of the filter, turn it round once or twice, so as to catch hold of the cotton, and then pull it up very slightly."

## Notes and Queries.

In conformity with numerous suggestions, we resume the plan of setting aside a column in the NEWS to be devoted to NOTES and QUERIES, to consist of questions and answers, or statements of difficulties and their solutions. We invite all who have difficulties or abnormal experiences, to state them clearly and concisely, and we shall be glad to receive solutions, suggestions, or notes from all whose experience may enable them to throw light on the subjects under discussion. This is a department entirely for our correspondents, and distinct in its aim and conduct from the Editorial Answers to Correspondents, which will be confined to their own column. One of the most distinguished art photographers in the profession opens the department with a photographic "conundrum."

### A PHOTOGRAPHIC CONUNDRUM.

SIR.—A lady and three gentlemen wanted to be taken together. You will see my position better if I describe how I disposed of the figures in group I had to compose. I first proposed to the lady to sit at one end of a small work-table, and to direct her attention to the gentleman I asked to sit at the opposite end—full of attention. Nearly behind the lady, her son, resting both hands on the table, leaned diagonally towards the gentleman with an enquiring look. Behind, but well seen, stood gentleman No. 3, forming the apex of the group. But I could not get him at all in tolerable focus (I did not mind him being slightly out); so I had another glass prepared. Now I took the group. All were good except No. 3, whom I now took by himself in the same pose, to be exchanged in printing with the blurred one. Now for the conundrum:—Oughtn't I to have shortened the camera (i. e., brought the lens nearer to the ground glass), or should I have pushed the camera nearer the object for the focus? O. G. R.

### THE TEXTURE OF HAIR IN ENLARGEMENT.

SIR.—I have photographed a fine glossy, flossy beard, fine in focus, and no movement. On having it enlarged—head and beard—the latter is rosy—coarse—not even like horsehair. What is the reason? ARTIST.

### MR. TILLEY'S SECRET.

BY W. T. BOVEY.

A COMMUNICATION from the above-named gentleman, recently published in the pages of the NEWS, presents an unmistakable indication that the secret possessed by the writer, in connection with combination printing, is to be made a subject of patent. My friendly advice in the matter is summed up in that cautionary word, "Don't!" The invention might contain the desirable elements of novelty, and cleverness added to boot, but there are so many ways of doing it, that the advantage of legal protection will be neutralized by an actual loss. I have clearly shown one way by which such work might be done, and now I give two more suggestions, which Mr. Tilley would do well to consider ere he purchases honours, and inflicts upon

\* Hart's testing apparatus will meet the case for English printers.—Ed. P. N.

himself the worry and anxiety which belong to every one who becomes a patentee.

The work of combination can be accomplished by an adoption of any of the old methods published. The trouble might be greater, but the cost of liberty to work them is absolute *nil*. And, after all, what more easily accomplished than success by new means? Supposing we cut a piece of tracing paper the exact size of negative, place these in juxtaposition, and, by the guidance of transmitted light, paint in the outlines of the figures; fill in the centres with opaque pigments, and the tracing paper becomes virtually a mask, which, attached to the view negative, leaves only to be carefully executed a print of the figure subjects on ordinary albumenized paper, cut exactly the size of negative. As with the tracing-paper before treated, adjust the albumen print edge to edge on the mask, and, if this last is properly painted, the figures, without any special attention to them, will be effectually protected from light.

Or a print might be taken on thin salted paper from the figure negative, and this converted into a mask. If desired to be made transparent in the unblocked-out parts, alcohol, with as much castor oil as it can dissolve without showing symptoms of oiliness, will answer the purpose required. The whites and lights above the deeper middle tints would, of course, require painting out. Place this mask on the negative, and proceed as per instructions just presented.

#### ALBUMEN AS A SUBSTRATUM.

BY R. M. S., M.D.

THERE is, I fear, no royal road in photography. From the glowing accounts in many of the back numbers of the NEWS of the advantages of an albumen substratum, I was induced to "go in for it." The result, after frequent and patient trial, was disorganization of the nitrate bath; that system was, therefore, abandoned.

Unfortunately, I cannot suggest any panacea for that great evil to photographers, a dirty plate; but after a variety of experiments I have found the plan proposed by Mr. Tunny, of Edinburgh, in the NEWS ALMANAC of this year, of immersing plates in nitric acid one part, and water ten or eleven parts, most effectual; and finally rubbing them on both sides with a few drops of tincture of iodine and strong ammonia, such as I last year published in your columns for removing stains from the hands, and polishing with a clean tuft of cotton.

Immersing plates in boiling washing soda certainly removes the varnish; but I look upon it as a fatal error: the plates so treated are often so irretrievably stained that no after labour will obliterate the marks. Mr. Keith's (of Liverpool) plan of immersing them in nitric acid one part, and methylated spirits of wine seven parts, is, on the other hand, a great success. In a very short time the plate is completely relieved of the varnish, and the trouble of after polishing reduced to a minimum. Mr. Tunny, in the article referred to, advised certain proportions of gelatine, ammonia, alcohol, and water as a substratum and substitute for albumen, believing them to be without risk to the bath. My experience has not been so fortunate, for already by their use I have rendered these baths, for the present, unserviceable.

The notion of preparing at once a whole boxful of plates, that should be ready at a moment's notice, was so tempting that, old hand as I am, I was seduced by the recommendation of so practised and able an expert as Mr. Tunny to venture upon a sea of troubles. The first two or three plates were all I could desire; but, alas! each subsequent plate showed signs of deterioration, till at length universal fog settled hopelessly over each future attempt, and the bath, under sun treatment and boiling, threw down a black precipitate of organic matter, and gave an infinity of trouble to restore it to anything like working order. So

that I am now compelled to return to all the labour of cleaning my plates as in former days.

The cause of my failure is possibly due to some blundering of mine, but I began with a faultless bath, and ended as I have described. I merely give my own experience for the benefit of my brother photographers, as a clean plate is the first *sine qua non* for successful work, either in the studio or field.

Mr. Tunny courteously replied to my request for further information on the subject than that supplied in his article in the NEWS ALMANAC, and advised a further addition of nitric acid; but I did not find that mend matters much, if at all.

I observe that a gentleman has lately been in trouble about his camera and tripod, and hinted the advisability of applying india-rubber rings to the tripod to save the bottom of his camera from injury. For each of my tripods I have a small square of clamped mahogany, about one-third of an inch thick, which I attach to my tripod with an ordinary thumb-screw, and on this I screw my camera, which effectually preserves it from friction, and enables me to secure any amount of rigidity I require.

#### ALBUMENIZED PAPER.

BY W. T. BOVEY.

PENDING more exhaustive comments, which I shall shortly offer, on this subject, I now briefly direct attention to a most curious fact. The price of the raw material is going upwards. The cost of albumenized paper, in sympathy with photographers generally, continues to go down—down to that starvation point which, reached, drives the unlucky producer into other and more profitable fields of industry. More singular still is the troublesome fact, that as the prices of the raw Saxe and Rives papers move upwards, so, in proportion, does their quality decline and deteriorate. The Saxe papers, from a delicate tint of pleasant blue, are now turned out an unsightly brown, indicating that they are not now manufactured entirely from linen.

The Rives papers still maintain their purity of colour, 'tis true, but those abominable metal spots, always so prevalent, are now supplemented with little imperfections that, unseen till too late to be remedied, grow into great abominations whilst the prints are being subjected to the process of fixing.

There are many other circumstances attending this question that demand a full consideration. At present, however, I may only beg your readers to suspend their half-formed opinions until they have placed before them whole facts.

#### RECENT RESEARCHES IN PHOTOGRAPHY

BY M. R. MELDOLA.\*

A SUBSTANTIAL contribution has been recently made to our knowledge of the action of light upon silver salts—a contribution which we cannot but consider as of the highest importance to photography, both as a science and as an art.

In the autumn of last year Dr. Herman Vogel announced,† as the result of some experiments that he had been making, that "we are in a position to render bromide of silver sensitive for any colour we choose—that is to say, to heighten for particular colours the sensibility it was originally endowed with." This discovery is such a decided advance that it will be interesting to trace it from the beginning. Dr. Vogel, in the first instance, found to his astonishment that some dry bromide plates prepared by Col. Stuart Wortley in this country were more sensitive to the green than to the blue portions of the spectrum. This result was so totally opposed to the generally received notions that the subject was submitted to further examination. In the next experiments a comparison was instituted between dry

\* *Nature*.

† *Poggendorff's Annalen*, vol. cl. p. 453.

bromide plates, and the same plates when wet from the bath solution of silver nitrate. The results showed a decided difference in the behaviour of the plates. The sensibility of dry bromide plates appears to extend to a greater extent into the least refrangible end of the spectrum than is the case with wet plates. In Dr. Vogel's plates, in fact, which received the spectrum formed by the battery of prisms of a direct vision spectroscop from a ray of sunlight reflected from a heliostat, and passing through a slit 0.25 mm. wide, the photographic impression of the spectrum, when developed by an acid developer, extended in the case of the dry plates into the orange, but with wet plates not quite into the yellow. The bromide plates prepared by Vogel, moreover, did not exhibit that increased sensitiveness for the green rays which characterised Col. Stuart Wortley's plates, and this led the German investigator to conjecture that the latter plates contained some substance which absorbed the green to a greater extent than the blue. To test this conclusion, one of the plates was washed in alcohol and water, in order to remove the yellow colouring matter with which the plate was coated, and it was then found to have lost, in accordance with Dr. Vogel's anticipations, its sensitiveness for the green rays. The peculiar action of the Wortley dry plates was thus shown to be due to the coating of colouring matter, and the next step made by Vogel was to seek some substance which especially absorbed in the yellow, and at the same time acted as a sensitiser by fixing the free bromine liberated by the action of light upon the silver bromide. Both these ends are fulfilled by the coal-tar colour known as coralline. A plate dyed with this substance and exposed to the spectrum exhibited two maxima of photographic action, one the ordinary maximum in the indigo (near G), and the other, almost as strong, in the yellow, thus affording complete confirmation of Dr. Vogel's views. Aniline green\* was next tried. This dye is stated to absorb the red rays, and a corresponding increase of sensitiveness for the red rays was observed, the photograph again presenting two maxima of activity, the one in indigo, and one in the red, coinciding in position with the absorption band of the dye. Thus Dr. Vogel's results may be summarised by saying that a dyed film of silver bromide exhibits maxima of sensitiveness in those regions where the colouring matter exerts its maximum of absorptive power; but the precise conditions under which these results can be obtained must be considered at present as unknown, since many observers, in repeating the experiments (among others Dr. Van Monkhoven†) have failed to obtain other than negative results.

In a communication made to the French Academy on the 27th of last month, however, the well-known physicist, M. Edm. Becquerel, stated that some experiments made at his instigation by M. Deshaies at the Conservatoire des Arts et Métiers had been productive of positive effects, and that some of Dr. Vogel's results with coralline and aniline green had been reproduced. M. Becquerel, however, does not confine himself to bromide films; similar results have been obtained by iodised collodion in which coralline was dissolved. A most remarkable action was observed also in the case of chlorophyll when this substance was used as a tinctorial agent. Although the collodion possessed only a faint green colour from the dissolved chlorophyll, the spectral image was of a much greater length than when plain collodion was used. Under these last circumstances the spectrum extended from the ultra-violet to between G and F, with the usual maximum of action near G, while with chlorophyll the region of strongest action extended from the ultra-violet to the line E in the green, and at the same time a weaker but yet distinct impression extended from E to beyond B in the red, with a strong band between C and D. By a close examination of the spectral image a second band of less intensity could be detected on the least refrangible side

of the band between C and D, and other still weaker bands appeared in the green. The most striking confirmation of Vogel's results is to be found in the fact, observed by M. Becquerel, that the band between C and D corresponds in position with the characteristic band of the absorption spectrum of chlorophyll dissolved in collodion. The same results were obtained by M. Becquerel with every plate tried, and with collodions containing different quantities of chlorophyll.

It must be admitted, then, that a film exerting selective absorption in intimate contact with a sensitive film of silver bromide or iodide affects the latter in those parts of the spectrum where the selective action is taking place. Here surely is a wide field for investigation, and one the importance of which will be at once obvious to the physicist. Practically also, when the precise conditions of action are made known, valuable results may be anticipated from the application of this principle to science and to art. Since the year 1842, when M. Becquerel photographed the whole solar spectrum from the extreme violet to the extreme red, and when Dr. J. W. Draper photographed the violet, blue, and extreme red, no successful attempts have been made to imprint the least refrangible end of the spectrum; and this, when we consider the great importance that the study of the solar spectrum has assumed of late years, and the painful or even dangerous character of prolonged eye observation, is to us a matter of wonder. M. Becquerel's result, it will be remembered, was obtained by a film of silver iodide, first insulated or exposed to diffused light, and then to the action of the spectrum. Here again is another question—the precise action of insolation on sensitive plates—demanding explanation at the hands of the physicist. The practical aspect of Dr. Vogel's discovery need not here be discussed at length. Attention may be called to the well-known difficulty of getting reds or yellows to imprint themselves in portraiture, a difficulty which now bids fair to be overcome.

Then, again, in what we must consider as a higher sphere of practical utility, great advantage to the study of solar physics is likely to accrue. In point of fact, the photographic method of comparing spectra described in a recent communication to the Royal Society now becomes available for the whole extent of the solar spectrum, and our knowledge of the true composition of the sun will be thus in course of time recorded permanently on "that retina which never forgets."

Great results have already been achieved by photography, and greater may be looked for. It must not be forgotten that in this most interesting branch of chemical physics we are in a period either of provisional hypothesis, or, worse still, of no hypothesis at all, so that valuable additions to our knowledge of physical and chemical laws should be forthcoming. The changes wrought by a beam of light on sensitive surfaces are sometimes physical and sometimes chemical. We may appropriately recall here the fact that mechanical pressure upon a sensitized surface of a silver salt acts in the same manner as a ray of light, giving a dark stain under the action of reducing agents. The experiment of Grove also, in which an electric current is set up by the incidence of a beam of light upon a prepared Daguerreotype plate, should not be forgotten. The equivalence between light and the other form of force has not yet been established, and it may not be going too far to conjecture that thermodynamics may possibly in the future have to appeal to the action of light upon a photographic plate. In the meantime we look forward to the promised continuation of Dr. Vogel's researches with no little hope.

## Correspondence.

### WOODEN BATHS.

SIR,—Should you think the following of sufficient interest for inserting, perhaps it may interest your readers. My trade is that of a carpenter and joiner, but I have

\* The green referred to is probably that known as "aldehyde green." The so-called "iodine green," as I have frequently observed, *transmits* a band in the red. † *Photographic Journal*, No. 25, June 20, 1874.

followed photography as an amateur for eight years—at times altogether. Having to go to different parts of the country, I take my photo things with me, and very often get several breakages. A short time back, I had a large glass bath broken, although in case and packed carefully, so thought I would make a wooden one, and try it. I have given it a month's trial, and it seems to answer very well indeed. I made it for 12 by 10 plates.

Get two pieces of wood fifteen and a-half inches long, sinking the front three-eighths of an inch at the edge, and five-eighths of an inch at centre. The back I sink three-eighths of an inch, level through—that is twelve inches front, the same leaving one and three-quarter inches each side. The back of bath I sink again six inches wide, one-eighth of an inch sunk down for dipper. The dipper I make one-eighth and one-sixteenth thick, so that the plate clears the back of bath. The dipper is halved together, and fastened with wooden pegs. At the centre of dipper I fasten a strip of india-rubber, to lift dipper out; this will bend down for lid to lay in its place.

I put piece of india-rubber between front and back of bath, then screw them both together. After back and front are fastened together, I place another piece of india-rubber on the bottom of bath, and screw on wooden bottom. When that is fastened on, I tongue the sides of bath; then make a clamp fasten on to them. When this is clamped on, I get strips of wood one and three-quarter inches wide by three-eighths thick, and screw on with small screws over the joint of clamp, this also forming front and back of bath into a panel. I then make a light frame to fit into back of bath, inside the border that forms the panel level with it—namely, three-eighths of an inch thick. When opened out, this forms a stand for the bath; when not in use, shut it up, with a small brass or wood button to keep it in its place. The border on top of bath I let stand up five-eighths of an inch to receive lid of bath. The lid of bath does not go further than the clamp. The clamped end runs up to the top of border. I fasten a piece of india-rubber on lid. Make a seven-eighths of an inch round rod to carry it with. Through the rod I have two thumb-screws, screwing its clamped end with two small springs on lid of bath, or, better still, two corks fastened to handle. The bottom of dipper will want to be three-eighths of an inch thick, or nearly so, to receive glass plate. The dipper answers well, keeping the plate steady in bath.

Two or three years ago, a correspondent of your paper wrote and said how he made a dipper with a stick out of the hedge, for a make-shift. After I saw that, having broken two or three glass ones, I made two wooden ones, and have had them in use till now. Adopted my present plan because of floating on the bath.

I have made my own varnish for some years—shellac and spirit—only I made some thicker, and gave this wood several coatings. Every joint was put together with it, save the india-rubber ones. I make my own camera stand, printing presses, &c. G. M.

## Talk in the Studio.

**SOUTH LONDON OUT-DOOR MEETING.**—The out-door meeting of the South London Society will be held, on Saturday, at Kingston-on-Thames, and Mr. S. Fry has generously offered to entertain the members at his residence at Surbiton Park Terrace, where his newly arranged landscape studio will be open to inspection.

**IRON SALT SENSITIVE TO LIGHT.**—It may be worth while to call the attention of our readers to a detail which might otherwise be overlooked. In Mr. Watson's article on the "Developer," in our last, he mentions the fact that he has found tartrate of iron sensitive to light.

**THE ILLUSTRATION COMPANY.**—A company with a view to protect all engaged in the pictorial arts from the constant

piratical raids made on their works is in course of formation. We shall have something to say on the subject in our next.

**GOVERNMENT PHOTOGRAPHY IN AMERICA.**—The *New York Nation* says:—"The addition of a photographer, supplied with suitable apparatus, is now considered indispensable to all Government expeditions of the first class, and the number of negatives accumulated in Washington as the result of the labours of Prof. Hayden, Lieut. Wheeler, Major Powell, Clarence King, Commodore Solfridge, Commander Lull, the United States Fish Commission, &c., has become really enormous. Many of these are 11x14 inches in dimension, and some of smaller size; while the stereoscopic views are almost countless. The peculiarities of a country and of its human and other inhabitants can thus be exhibited in a very satisfactory manner, and the whole forms a series of illustrations of wonderful interest. It is greatly to be regretted that no provision is made by Government for the publication of these pictures, so that they may be acquired by those who wish for them at a reasonable price. They are now to be had only by special favour of the heads of the departments, and a complete series cannot be obtained without great difficulty. A few sets might be distributed gratuitously to public institutions, others sold singly or collectively to individuals, at cost price. It is quite safe to say that the series of large plates amounts to over a thousand, while of stereoscopic pictures there are two or three times that number."

**CLEANING VARNISHED PLATES.**—Mr. C. A. Palmer, in our *Philadelphia contemporary*, says:—"I have seen many ways of cleaning off varnished negatives, but of course like my way best; and as I have never found any one using it, only as I have taught it to them, I will give it for the benefit of all. I proceed as follows:—I take my varnished negative and pour on it a little concentrated ammonia, rubbing it well over the surface; then, setting it in a level place, pour a little more on the centre of the plate, and prepare another the same way; then lay the varnished sides together, and serve another pair the same way; continue so doing till I have a dozen or two in the pile. Then set a weight on top and let them lay an hour or so, when the film will easily come off, and, after thorough rinsing, the plates are ready for albumenizing. I cleaned and albumenized fifty quarter glasses in a little over an hour a short time since. It is much the quickest, and I think the cleanest, method I have ever seen published."

**TRANSPARENT PARCHMENT AS A SUBSTITUTE FOR WINDOW-GLASS.**—According to M. d'Argy, of Paris, it is possible to render parchment sufficiently waterproof, and, at the same time, translucent, that it will become a substitute for glass. A design may be produced on the parchment by means of paint, photography, or chromo-lithography, or the sheet may be simply stained of any desired tint. One or more coats of waterproof and translucent varnish, or composition, applied carefully, protect the design, and render the parchment diaphanous. M. d'Argy asserts that in this manner an article may be produced adapted to all the various uses of window-glass, and capable, from its elasticity, of withstanding blows which would destroy glass. Unfortunately, however, he does not supply the name of the varnish which will render the parchment transparent, and as he does not intend to proceed any further than provisional protection, I suppose he has given up all hope of making a marketable article. But if it could be done, there are many circumstances in which painted parchment windows would be serviceable. Can any of your readers help with suggestions?—*English Mechanic*.

**SCIENTIFIC INVESTIGATION ON PHOTOGRAPHY.**—A writer in *Nature* says:—"On consulting books on practical photography, any one who pretends to any knowledge of chemical science cannot fail to be struck by the empiricism of the various formulæ proposed, and a feeling akin to regret is experienced on reflecting that this fascinating and useful art has reached its present state of perfection by processes which have been essentially methods of trial and error. The large number of practitioners, both professional and amateur, now engaged with this subject ought surely to produce from their ranks investigators willing, as we know they are able, to take up the purely scientific aspect of the subject. The harvest reaped by such an investigator would surely repay him, for we are of opinion that in the theory of the sensitive film lie hid some of the fundamental truths of molecular physics."

**SENSITIZING GELATINE PAPER.**—This is accomplished in a solution of one part bichromate of potash in twenty parts of water. The purer the bichromate salt the better the paper.

If small sheets of eighteen to twenty square inches are to be sensitized, the above solution is poured into a zinc or porcelain dish, the bottom of which should be covered to the depth of half an inch at least. The gelatine paper is dipped into the solution and left there until it gets soft, which generally takes thirty to forty seconds. It is then taken out and laid, gelatine side down, on a well cleaned glass plate. By rubbing with a piece of india-rubber, not too hard, the greater part of the liquid is removed from the paper. On lifting the paper from the glass, it has a fine, smooth surface, on which there will be no streaks or drops formed afterward, as it is already half dry. It is then hung, on laths provided with pegs, to dry. Thus prepared, it will bear a much higher temperature than when the solution is not pressed out. In cold weather, the paper can remain some minutes in the chromate bath; it should be left there until soft and pliable. In preparing large sheets, another method must be employed. A sufficient number of thin strips of pine wood, three-fourths of an inch wide and long enough to rest on the opposite side of the dish, are saturated with shellac varnish, and, when dry, rubbed with cocoa butter, and then polished with an old linen rag. Horizontal sticks are put up in the preparation room with notches to receive these strips. The dish for a large chromate bath is best made of stout zinc. A sheet of gelatine paper is allowed to float on the bath, gelatine side down, until soft, when one end is lifted up and laid on one of the pine strips; another strip is laid on the paper, and the two clamped together. The paper is then drawn, face down, over a glass rod or tube fastened to one side of the dish. In this way small air-bubbles are removed, as well as a large portion of the solution. The paper is now hung up by placing the strips of wood clamped to it in the notches on the horizontal sticks. A third strip is pressed gently against the back of the paper just below the others, and drawn down to the lower edge, thus partially removing the solution from the back. It is then elamped to the lower edge. In this manner, says the *Photographische Archiv*, a sheet of paper five feet long may be sensitized in less time than it takes to describe it. The chromate bath should be kept covered to keep out the dust; and before using it, a piece of blotting-paper may be drawn over the surface.—*Scientific American*.

**RETOUCHING AT NIGHT.**—Fr. Wendling says:—"Doubtless many photographers have tried to use artificial light for retouching the negative; but it seems without result. I never read or heard of success. I have made, also, different efforts in that way; but in the last winter, before Christmas time, work pressed me to make another experiment. I tried a petroleum lamp, with round burner, and fastened to it—in order to secure a stronger light, and parallel beams—the parabolic mirror of my magnesium lamp. I gained an intense light, to be sure; but, on retouching, I felt my eyes very much affected, not being able to work long. Now, I remembered that once a watchmaker told me he was able to work easily in the evening since he employed the light blue glass (called optical glass), and I followed him in using that material. The effect was excellent, and since, I have retouched a great number of negatives, in the winter past, at night. As the parabolic (or spherical) mirror concentrates also the heat-beams, it would, perhaps, be an improvement to use, instead of the blue glass, a "euvette," containing a solution of sulphate of copper with ammonia, or Prussian blue dissolved in oxalic acid. I think, if you publish this, that the apparatus will, in a short time, be in every photographer's hands, because it is a welcome requisite, although it may be considered both tough and very simple—a very egg of Columbus.—*Philadelphia Photographer*.

## To Correspondents.

**BREAKWATER.**—The cause of your cards being peppered with small spots is very manifest. We have pointed it out very many times lately. The spots are due to the particles of bronze powder from the "gilt" printing at the back of your cards becoming detached, and resting on the face of the print. This so-called gold printing is effected with a bronze powder containing sulphide of tin, and each particle resting on the print produces a spot of sulphide of silver. You should banish all the cards so printed from your establishment straightway.

**G. TROUBRECK.**—We regret that we are unable to recommend any one for the purpose.

**H. C. C.**—Your negative reached us in a thousand fragments, the small troublesome spicula of which still hang about the cloth covering of our writing table. Negatives to be sent by post should always be placed in a wooden box sufficiently strong to resist the pressure of stamping and other rough usage of transit. Cardboard or millboard at each side of a plate of glass is simply useless for postal transit. We can form but little idea from the broken fragments of the negative of the precise trouble, but, so far as we can judge from small pieces and your description, the trouble is a metallic silvery deposit in the shadows, under, rather than upon, the film. Such a deposit is generally the result of using a damp or dirty plate, and the best remedy is precision in this respect. Of course other conditions will conduce to the production of the result, a nitrate bath charged with organic matter materially tending in that direction. Sunning the bath, or treating with permanganate, as we have repeatedly described in our *YEAR-BOOK*, will rectify the bath.

**SIDE-LIGHT.**—We cannot, of course, explain what the author means, any further than he has explained himself, especially as we have not the work at hand for immediate reference. In the case to which you refer, we presume that the background is placed in a diagonal position across one corner of the room, and the camera directly, or nearly, opposite to it at the other corner. In this case, a sitter, with back to the side-light, together with background, could be included by the camera. 2. The mode of treating a bath to which you refer has not been found to answer in practice generally, nor to possess the advantages claimed for it.

**IL TALISMANO.**—The white line round the figure in double printing, with Edwards' printing frame, may arise from several causes. The mask may be imperfectly cut out, or it may be imperfectly adjusted, or the frame may be a little out of order, and so not secure perfect register.

**AMATEUR.**—Bichloride of palladium is generally sold in concentrated solution of uncertain strength. When we have used it we have diluted this concentrated solution until it was the colour of pale sherry when required weak, and of brown sherry when required strong. As the salt is not usually met with in crystals, we cannot give you more precise information, or state the number of grains to the ounce required by a solution.

**SOUTH DEVON.**—You would not find white of egg a good substance for mounting prints; it has not body enough, and is not sufficiently tenacious. Even if it had the proper adhesive qualities, it would not be wise to use it, as it contains sulphur.

**JOHN REAY.**—You do not state what kind of hints you require on the construction of a glass room. The dimensions you mention are pretty good, but we should have preferred it a foot or two longer and a foot or two narrower. You do not state whether it is to be lean-to or ridge-roof. If you can have either, and there is an open expanse on both sides, a ridge-roof will possess advantages. If only north light is unobstructed, then select the lean-to form, the side-light facing north. Keep the eaves low—six or seven feet will be ample—whilst the highest part may run up to twelve or fourteen feet. About six feet at each end of side and roof opaque, the remainder glass. Glass on side to within twenty or twenty-four inches of ground.

**P. S.**—There are a variety of methods of dealing with a varnished negative which has been insufficiently intensified. You may remove the varnish by repeated washing with alcohol, and then using pyrogallic acid and silver dissolved in spirits of wine instead of water to intensify. But this is a somewhat troublesome method. The simplest plan, and, in our hands, the most satisfactory, consists in moistening the varnished surface with alcohol, and then applying tincture of iodine, made by dissolving six or eight grains of iodine in an ounce of alcohol. This is applied to the varnished surface. In a few seconds the image assumes a deep olive tint, very non-actinic, and capital for printing purposes. As soon as this tint is secured, the negative is rinsed with alcohol, and dried by the fire, and is again ready for printing. Care should be taken to stop the action of the iodine at the right point, as if it is allowed to go on, the negative becomes a pale, feeble yellow, which easily transmits light, and the negative may, in such case, be found actually weaker than before.

**QUERY.**—The dish containing the water into which the prints were placed has been contaminated with hyposulphite. No other cause, that we know of, except the action of hyposulphite, in this or some similar manner, would have caused similar stains.

**T. S.**—We do not remember the recipe in question. Our correspondent had better obtain all the numbers he has lost, and so secure the one required amongst the rest.

**C. J. E.**—Thanks. In our next.

**A PRINTER** writes to endorse Mr. Hooper's letter in our last; but he does not add any fresh information, hence it is not necessary to print his letter.

**THE STATUS OF PHOTOGRAPHY.**—We have received a letter on this subject without any signature; which will, however, appear in our next.

Several Correspondents in our next.

## The Photographic News, August 28, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

GLASS POSITIVES VERSUS PAPER PRINTS.—NEW USES OF PHOTOGRAPHY.—PRINTING BLOCKS OF CARBON TISSUE.

*Glass Positives versus Paper Prints.*—The question has often been mooted whether we have not lost much by discontinuing to employ the Daguerreotype process for portraiture. The Daguerreotype pictures of a quarter of a century ago were often far more delicate and faithful representations of personages than the carte-de-visite pictures of to-day, and it is very certain that, so far as scientific records are concerned, such as it is important shall not dilate or contract after depiction upon the sensitive film, the reception of the image upon a rigid silver plate is by far the most reliable method we have. Glass positives, like Daguerreotypes, are also, we fear, rapidly becoming things of the past, and this is also a fact to be regretted. Any one taking up an album in a humble household in some little country district, and comparing the vulgar black-and-white pictures therein with the glass positives that hang around the walls, cannot fail to be struck by the vast superiority of the latter, which are softer and more detailed than the common paper productions. The latter, it is true, have many advantages, but then they must be well executed. A photographer of modest capacities will produce far more presentable portraits by the positive collodion process than on paper, and this fact, coupled to the circumstance that the former are also more durable than the generality of albumenized prints, must not be lost sight of. The reason for this lies, however, less in the superiority of the glass positive than in the miserable character of the cartes-de-visite executed at some of our little market towns. Really, when the amount paid is but a few shillings per dozen, better work might be done than is performed by a large number of country photographers, who know very well what good pictures are, and how they are to be produced. We have constant discussions about raising the status of photography; but until there is a thorough *esprit de corps* throughout the profession, and an understanding to produce good and durable pictures, free from the commonest faults of photography, little can be done to raise the art to its proper position. So long as photographs are merely taken mechanically, and printed mechanically, without the exercise of taste, judgment, or skill, photographers will be considered as mere mechanicians, who employ their tools with more or less skill.

*New Uses of Photography.*—We are always happy to see new applications of our art, even if they occur in the minor bye-ways of industry or commerce. Our readers are tolerably familiar with the sheets of note-paper to be purchased at the country stationers, bearing on the front a lithographed view of some building or spot of interest in the neighbourhood, to be employed when sending a letter home from any district one may be visiting. Instead of these cuts you may now procure note and letter paper ornamented with photographs of landscapes and buildings; and these obviously form a much more pleasant souvenir than the coarse fancy sketches we have seen and despised so often. Another photographic novelty deserves mention. To attract visitors to various summer resorts, hotels often set up placards at railway stations and other public places making known the beauties of the neighbourhood. Cliffs of dazzling whiteness are surrounded by waves of azure blue, while in the neighbourhood is seen the famous hotel itself, a lofty and spacious building situated in the loveliest of grounds. Everybody has seen these enticing pictures, and has found reality scarcely equal to the fancy sketch placed before their eyes. Recently we have seen instances of these brilliant tableaux being superseded by modest photographs; and a frame of these are certainly more

encouraging to a tourist prospecting a visit to any district, than the blue and white paintings often exhibited. A waterfall, cascade, rocky defile, or broad lake is skilfully portrayed by means of the camera, and the result is a production in which everybody may have perfect confidence.

*Printing Blocks of Carbon Tissue.*—Printing with greasy ink from a carbon print can never be undertaken in the same way as when a film of bichromated gelatine only is employed. Several foreign processes have lately been made known, in which it is suggested to employ a sheet of pigmented tissue for producing the printing block in lieu of taking the trouble to prepare a mixture of bichromate of potash, or chrome alum and gelatine. The sensitive film is exposed to light under a cliché, and is then sponged and inked up with a roller to which printer's ink is attached, and it is stated that the ink will attach only to the solarized, or hardened, portions of the film. This is perfectly true, supposing there is no pigment in the film; but when carbon tissue is used, there is lamp-black all over the surface, and greasy ink, it will be found, will attach itself to the pigment, just as much before solarization as after; for naturally enough, whatever action the sun may exert upon the bichromated gelatine, it has none whatever upon a pigment such as lamp-black.

### FRENCH CORRESPONDENCE.

THE Academy of Sciences has lately received several communications interesting to photographers. Among these I may mention, first of all, a long and remarkable memoir of M. Edouard Becquerel, entitled "Action of rays of different refrangibility upon the iodide and bromide of silver: influence of coloured mediums." In this work the learned professor, to whom the photographer owes much useful teaching, gives an account of some ingenious researches upon the iodide and bromide of silver under various conditions; as upon the surface of a silver plate, as in the Daguerreotype process, or upon paper by double precipitation, or incorporated in collodion, or gelatine, and employed both in the wet and dry condition. Further, M. Becquerel passes in review the results obtained by Dr. Vogel, and explains the chemical phenomena produced by the presence of coloured matters mixed with bromised or iodised collodions. The importance of a memoir of this description, which includes all known up to the present day about these two salts, which form the basis of all photographic operations, cannot be overrated. As it is impossible for me to reproduce the entire paper, I merely allude to it here so as to bring it to your notice in case you may desire to print in *extenso* from the *Comptes Rendus* of the Academy.

M. Jules Girard has also communicated to the Academy an interesting photographic paper. For some time past M. Jules Girard has made happy application of photographic processes to microscopic study, and the work he published in 1870 under the title of "The Camera and the Microscope," will not be forgotten. The author, who has continued his useful work, exhibited, on Monday last, several photographic reproductions of different crystalline objects. Among other things, he has reproduced, and enlarged to twelve diameters, some crystals of sal-ammoniac and bichromate of potash, two substances in which photographers are obviously interested.

M. Girard, in describing his method of operating, commenced by declaring that it was best to work by means of transmitted light, if possible, supposing it is not too intense. He employs an apparatus composed of a metal plate fixed to a stand bearing the camera. This horizontal plate is formed of different pieces upon a winding screen, so that they can be shifted to and fro at the same time as the camera. Then upon the plate is fitted the lens, about a centimetre in diameter, combined so as to give an enlargement between eight to twelve diameters; secondly a spring pincers, to carry the object or the glass upon which the

salts are crystallized; thirdly, a strip of blue cobalt glass, to impart a favourable monochrome tint to the object; fourthly, a plane mirror, for reflecting, which, like all the rest, is moveable.

According to the transparency of the crystals, the period of exposure varies from a second to two or three minutes. To obtain greater relief, and to show the forms of the crystals, an oblique light is secured by inclining the mirror. Although the brilliant effects of polarized light appear of little use in photography, they allow, in certain instances, of showing the objects upon a black ground, so that their delicate details are better seen. The polarising apparatus is composed of two pieces, the polariser and the analyser, the first being placed in front of the object glass, the latter between the camera and the object glass.

When you want to operate, a little of the solution of salt is poured upon a strip of glass, and dried on a levelling-stand to get the crystals of uniform thickness. Solutions of different concentration should be tried.

Fibrine of blood dissolved in aqueous solution of sea salt presents certain characteristics which lead one to suppose it is a substance intermediate between albumen and caseine; by freeing the solution from the salt it contains, and concentrating it rapidly by distillation, *in vacuo*, at a temperature of 45° Cent. M. Armand Gautier has obtained a neutral substance which possesses most of the qualities of ordinary albumen, and, on analysis, it gives identical results. This albumenized substance from fibrine coagulates at a temperature of 61° Cent., whilst egg albumen only coagulates at 73°. A very singular circumstance M. Gautier mentions in connection with this substance, which has been confirmed by M. Beauchamp, another chemist, *viz.*, that the white of egg contains, besides incoagulable matter, two distinct coagulable albumens, one of which coagulates at 60° or 63°, and the other at 71° or 74°. The albumenoid from fibrine is analogous to the albumen which coagulates at the lower temperature.

Medical men have already pointed out that the fibrine of very young animals, or of those weakened by bleeding, is easily soluble in warm water, forming a solution like white of egg. M. Wartz has also shown that on putrifying fibrine, a notable quantity of albumen is yielded.

It would be well to try the albumen of M. Gautier in photography, to see if it could be substituted for egg albumen with advantage; it would, of course, be much cheaper, because of the large quantity of blood always obtainable.

A painter who works at retouching in one of the principal photographic studios of Paris, and who has studied the question of mounting photographs, has succeeded in preparing a new and suitable material. The "Colle Ramie" is imperishable, very adhesive, and undergoes no chemical action. I am about to institute experiments with it, and will forward you a sample for a like purpose.

M. Leon Vidal perseveringly continues his polychromic researches, and I have lately received from him a further specimen, which is of a wonderful nature. It is a portrait of a consul-general in full uniform, measuring twenty-seven centimetres in length, with a head of four centimetres. The coat is green, richly embroidered in gold, and covered with decorations of enamel and silver, with ribbons of various colours. The trousers are white, with a gold stripe, and all the tints are well executed, and the colours faithfully reproduced. The ornaments are wonderfully striking, and, altogether, the picture seems to be the production of a most skilful painter.

We learn that, not content with the practical results already obtained, M. Vidal is actively occupied in making his process applicable for printing with greasy ink. Instead of printing consecutively upon pellicles differently tinted, to be superposed afterwards, he produces monochromes on stone, in the same way as chromo-lithographs are obtained.

*L'Union Centrale des Beaux Arts appliques a l'Industrie,*

whose work was interrupted by the war, and which has now been re-established under the presidency of M. Guichard, has just opened its fourth exhibition at the Palais de l'Industrie. Photography takes an honourable place, and is represented by some beautiful enamels of M. le Comte de Roydeville, and MM. Gugenheim et Forest, and by some fine landscape and animal studies of MM. Quertier et Cie, Achille et Alexandre Quinet, Raphael, &c.

ERNEST LACAN.

## PHOTOGRAPHY IN CONNECTION WITH ASTRONOMY.

BY COLONEL STUART WORTLEY.\*

HAVING been asked by the Astronomer-Royal for some information in connection with photographic processes with a view to their being used for the transit of Venus, and having had the advantage of discussion of the various processes with my friend Captain Abney, who has been in charge of the transit photographic work, I made at various times during the past summer a number of experiments in solar photography, the result of which may possibly be of use to future workers in this branch of science.

Taking the ordinary commercial collodions manufactured for photographic processes, we are at once struck with the difficulty of getting accurate micrometrical measurements, in consequence of the varying amount of contraction and expansion possessed by the collodion film in its wet and dry states. To counteract this difficulty it is necessary to make the pyroxyline with the maximum of water added to the acids which they will bear without dissolving the cotton when immersed therein; and it is also desirable to reduce considerably the proportion of nitric acid to sulphuric, with the object of obtaining a film which shall neither contract nor expand when either wet or dry. By using such a pyroxyline I have been enabled to make a film on which the most delicate micrometrical measurements can be registered with absolute perfection.

The next point to be considered in connection with astronomical photography is the radiation and halation produced where the bright and dark parts of the picture meet. This appears to proceed from two different causes: one, which we may call "halation," being the reflection of light back from the glass that supports the film, into the film itself; and the other, which I will call "radiation," and which appears to be an action in the sensitive molecules of the film itself, and occurring no matter on what support the film may be laid. Halation from the first of these two causes can be prevented in two ways: one method being to place a dark pigment on the back of the glass plate, and in optical contact therewith; and the other, and far preferable one, to stain or dye the film itself with such an amount of orange or red colour as shall stop the rays of light from getting down to the glass and being thence reflected.

But the radiation which takes place in the film itself is much more difficult to subdue, cannot be subdued by mechanical means, and can only be subdued by the use of certain chemicals in the film, differing somewhat from those in use in the ordinary photographic processes.

Before pointing out what I consider the best means of avoiding this injurious halation, I will point out what I consider it to be, and why I consider it to be so. I think the radiation in photographic films, which is so unpleasantly apparent when a bright object is photographed in close proximity to a dark one, is due to what I may call a "creeping" of the superabundant light, which has done its work on the bright object, over and into the darker portions of the picture. To illustrate this argument the following fact in connection with dry-plate photography should be borne in mind:—If a landscape photograph consisting of trees and sky be taken in a bright and actinic

\* Read at the meeting of the British Association at Belfast.

light, and when a short exposure is, therefore, only necessary, there will be on a rapid dry plate but little radiation; but if the same view be taken in a dull light, and when the actinism is infinitely less, the longer exposure required will certainly produce a great amount of radiation from the sky over the trees. Now the sky, even in a dull light, would be impressed on the film tolerably rapidly, and the necessity for the long exposure is in order to get the detail in the darker parts of the picture, and the radiation is thus produced by the creeping of the superabundance of light that has already finished its work on the sky over the dark parts of the picture which require the prolonged exposure. That this "creeping of the light" does take place, the following experiment will, I think, show with certainty:—

In order to find out which of the salts of silver were least liable to give this radiation, I have experimented with a very large number of them, to which I will presently allude; and the following singular fact was discovered by me in connection with the chloride of silver, which salt has much more tendency to give radiation than any other that I have experimented with. I had found that a sensitive film which contained a chloride was always possessed of less satisfactory keeping qualities than one from which chloride is absent; and in course of some experiments on the various keeping qualities of plates between exposure and development, I came across the following singular fact:—A dry film containing a considerable quantity of chloride was, after exposure, put in half—one half developed immediately, and the other half put away in the dark for forty-eight hours. It was found that on the half of the plate that had been kept in the dark for forty-eight hours the "blurring," as it is called by photographers, was considerably greater than on the half plate that was developed at once; and on repeating the experiment several times I was enabled to convince myself that the action of radiation, or what I have called the "creeping of light," on to the dark parts of the picture continues after the film has been removed from the action of the light, and after it has been put away in the dark. I have noticed this with chloride of silver only, but I was thus led to investigate the behaviour of other salts of silver in connection with this radiation of light.

No photographic process gives such good and rapid dry plates as the one in which an emulsion is made of bromide of silver formed in the presence of a large excess of the nitrate of the metal; but when we use the bromide alone, it is unfortunately strongly addicted to the blurring before spoken of. We can, however, entirely counteract this tendency by the use of other salts of silver. I will not take up your time by going into very minute details on this point, but will merely say that I have found that the addition either of the malate, succinate, fluoride, or iodide of silver to the bromide will, if used in the proper proportion, give a sensitive film from which radiation shall be entirely absent, and that their suitability to the purpose is found in the order in which I have written their names; and with a film containing a large proportion of malate of silver I have been enabled to take subjects which it would be impossible to take by any other method, owing to their strong contrasts of black and white. It should also be noticed that these salts have a peculiar effect on the colour of the finished negative, the malate giving a golden brown, the succinate a red brown, the fluoride a pink, and the iodide a delicate green. It is also a great preventive of radiation to add nitrate of uranium to the emulsion; and, whatever other salts are used, this should never be omitted. I may also mention here that I have found these various salts to act in a remarkable manner in connection with the colours of the spectrum, and to give peculiar results in connection with some of the more difficult lines thereof.

There is one final point as to the obtaining of good astronomical photographs. It appears to me to be essential that they should be developed by the strong alkaline method

of development which was introduced by myself in the course of last year. It is impossible, with the old method of development to obtain results in any way as satisfactory as those obtained by my new method. Not only is there a very great increase of sensitiveness obtained, but the development is unusually certain and rapid; and where the sun has to be photographed it has a peculiar effect in giving the outer limb clear and sharp. Captain Abney has, after many experiments, decided on using my method of development for the dry plates used at the transit of Venus; the formula being a saturated solution of carbonate of ammonia with sufficient pyrogallie acid, and bromide of potassium if required.

## ON THE MULTIPLICATION OF MAPS AND PLANS IN THE FIELD.

BY CAPT. ABNEY, R.E., F.R.A.S., F.C.S.\*

OUR president has already remarked on the necessity of a military man knowing geography. I venture to think that topography is even more necessary. A very little thought will convince those of my hearers who have not hitherto considered the subject, that the more perfectly the officer commanding an army in the field knows the ground on which he is about to give battle to the enemy, the greater his chance, if not of securing victory, of at least making the best fight possible.

I will not take up time by enumerating instances; even recent autumn manoeuvre experiences may possibly occur to some of you. Now, for instance, the Prince of Wales, on the point of being taken prisoner, escaped by an intricate pathway across a bog, over which his enemy was afraid to follow him; and you can understand how a deep, unknown ditch may foil a charge of cavalry; and, in short, how, in a hundred ways, a good knowledge of the country is desirable, not only for the general in command, but for all the officers under him. Now this knowledge can, in but the very rarest instances, be what is called "personal" knowledge; and if it should happen that there is one officer in any army who is well acquainted with the field of battle, it is absolutely certain that but very few will, and they probably will not be the men who are best able to use that knowledge.

But if every officer can understand a map, and if a special map be made of the part of the country required to be known, and if this map can be multiplied so rapidly that within a few hours after it has been completed, a clear and intelligible copy can be put into every officer's hands, then we get as near as possible to the condition of perfect local knowledge throughout the army. And here I would remark that, though maps of civilized countries can be obtained, more or less accurate, yet they are necessarily on a very small scale, and a map, however good, on a scale of ten miles to an inch, cannot possibly show, for instance, such a wall as helped us to win the battle of Meane.

The Prussians, with that forethought which so entirely distinguishes their War Office, went to war with France thoroughly prepared, with maps revised to the latest moment—so, at least, it is said—and it is not known whether they had to resort, on any large scale, to the operations of what we term "*reconnaissances*," but they invariably made the officer in charge of any post map out roughly the country close round it, as a guide to the generals, in regard to local details. I will, however, exhibit such a piece of *reconnaissance*, such as the officers of the Royal Engineers are taught to make; and when I tell you that we have at present in the army systems by which this kind of work can be multiplied at the rate of one hundred an hour in the field, you will see that at least we have made some advance since the time when all the officers of the Engineers were kept up all night, copying by hand

\* Read at the meeting of the British Association at Belfast.

the rough sketch, almost from memory, which guided Sir Colin Campbell into Lucknow at his relief; or, again, since the time when the Duke of Wellington was able to take his army across the stream which runs past Tarego, from a sketch taken by an Engineer officer while at full gallop. In the hope that a more precise description of the method employed may be interesting, this paper has been written. And here I may say that the duty of multiplication of maps has been placed in the hands of the Royal Engineers, as the professional training of the officers is such as renders them more practical in the methods employed, and also the Sappers under them for this particular purpose are men whose trade is that of lithography or photography.

In order to reproduce plans without the aid of light it is evident that but two methods are open—first, either the plan must be drawn in copying-ink; or, second, in an ink suitable for transfer to stone or zinc. The first plan is inadmissible, as it is almost impossible to get more than six copies from the original. The other method is that which has hitherto appeared most practicable. Those who are familiar with the subject of lithography and zincography will know that any subject meant to be reproduced must be drawn in a particular kind of greasy ink on a paper specially prepared for it, and that the greatest caution is required to prevent finger marks, caused by hot fingers touching the paper, from being transferred with the drawing. The prepared paper is also spoilt by moisture. The ink is generally in an inconvenient form, requiring rubbing up with water before being used. Evidently, then, there was a difficulty in the way. I had happened to direct my attention to the subject for other purposes besides that indicated, and after various experiments I had the good fortune to make an ink, not greasy, but yet capable of being transferred to stone or zinc. It was also unnecessary to use the prepared paper, the subject readily going down from the ordinary kind. This had important bearings, as it was immaterial if the fingers touched the paper, as the greasy markings from them could be destroyed before transferring it to the stone.

The colour of the ink, which was my great difficulty, is a black, and after transfers are taken from it the original remains nearly unharmed. It has been adopted into the service for field work, as, indeed, it has for the *dépôt* at Chatham and in the Surveyor-General of India's office. I exhibit some results from a *reconnaissance* done in the field with it. All that is necessary in using it is to keep india-rubber from the paper. If this be attended to it will go down cleanly and well to the stone or zinc. The stone or zinc plate is slightly warmed, the grease destroyed by an alkali, and, when damp, it is placed on the one or other, and passed through the press, when it will be found, in rolling upon the impression, that an exact *facsimile* of the sketch is produced. Three transfers can be taken from the same sketch, and within one hour from the time of receipt of a drawing fifty copies can be issued. It has not been deemed advisable to adopt any other process but this in the field, though, doubtless, improvements in the method will be developed, and render reproduction still more easy.

The next branch to which I wish to call your attention is that of reproduction by means of photography. It frequently happens that one plan of a district may have been obtained, and it may be necessary to reproduce it on a large scale or on the same scale.

It should be remarked that enlargements from an accurate map—say from the one-inch scale to the six-inch scale—are often most useful, enabling the reconnoitering parties to put in details without absolutely re-surveying the ground. As a rule, a negative is taken by the ordinary processes, and, if only three or four copies be required, prints are made on common salted paper, or on linen, a supply of both being taken in the field. Preferably one would use the former, and mount it on the latter. When over half-a-dozen copies are required we use a species of photolitho-

graphy. That method practised at Southampton was originally adopted, but it has again been our good fortune at Chatham to introduce a modification into the system which is easier to apply in the field. This I have called "papyrotypy."

The following is a brief description of Sir H. James's method:—Paper is coated with gelatine, and rendered sensitive to light by the addition of bichromate of potash. The action of light on this salted gelatine is to render it insoluble in water, and also incapable of absorbing water. Thus, if this sensitive paper be placed under a negative of which the black lines of the original are represented by transparent glass, and the whites of the paper by an opaque deposit of silver on silver and mercury, the lines printed on the gelatinised paper will become insoluble in any water, either hot or cold, whilst the white portions will absorb cold water, and actually dissolve away in hot. Up to this stage this process and papyrotypy are alike. In the Southampton method, the paper, after being printed upon by the action of light, is covered with a very fine layer of greasy and resinous ink. The back of the paper is next floated on hot water, thus penetrating to the gelatine, softening it, and rendering it liquid. It is then taken on to a flat inclined surface, and by the aid of warm water the soluble parts are all sponged away, carrying with them the ink that covered them, and leaving the lines represented by black ink in minute ridges of gelatine. Evidently now we have a drawing in greasy ink ready to be transferred to stone or zinc.

In papyrotypy the paper, after being taken from the printing frame, is immersed in cold water at once, thus stopping nearly all further action of light, for bichromated gelatine is only *slightly* sensitive when wet. It is blotted with blotting-paper to get rid of surface moisture, and then a soft gelatine roller charged with greasy ink is passed over the surface. Now it must be borne in mind that where the light has acted there *alone* the gelatine does not absorb water, and as water repels grease, the greasy ink will only take on those parts which have been acted upon by light; hence we have a facsimile of the original. Owing to the expansion of the gelatine when wet, the copy is sometimes finer in detail than the original. The benefit of this plan in the field is that no hot water is requisite, and that after one transfer has been taken upon zinc or stone, another can be rolled in on the paper and a fresh transfer made. Another point I lay stress upon is that the greasy ink is on the surface of the paper, and not on ridges of gelatine. After transfer to zinc or stone as many copies as may be required can be pulled off at the rate of seventy or eighty an hour from one press. This process has been adopted, and is found to answer well for the purpose to which it is applied.

(To be continued.)

## THE PRACTICAL PRINTER IN AMERICA.

### V.

#### MANIPULATIONS.

VERY much more depends, in the mode of working, on the precise details of manipulation, than at first sight appears. Success and economy are both secured by going the right way to work. Mr. Hearn's hints are very valuable, especially for working on a large scale. He says:—

"Unless photography is practised on a very small scale, the paper had better be floated in whole sheets, and not cut up, as is sometimes done, into half and quarter sheets.

"For the purpose of silvering or floating the paper, a porcelain dish should be obtained, and thoroughly cleaned before use; and when the printing solution is properly filtered, it should be poured into it.

"Bubbles forming on the surface of the solution after it is poured into the dish should be skimmed off—if they

do not break of their own accord—before the albumen paper is placed on the bath. If the bubbles do not break of their own accord, pour about an ounce of ninety-five per cent. alcohol into the solution, and stir well with a glass rod; or always keep a lump of camphor in the bottle into which the solution is poured after use.

“Considerable mechanical skill is required in silvering the paper properly. By proper treatment of the paper whilst silvering, many of the photographic printer’s troubles are, in a great measure, lessened.

“Many photographic printers, in placing the sheet of paper on the bath, take hold of two corners diagonally, and place the centre of the sheet on the bath first, and then in turn the two sides. In this way there will be a row of bubbles (minute in size) at that place where the paper first touches the bath, and which will take all the spare breath of the printer to break by blowing, and while this blowing is being done the paper will be silvering unevenly.

“Lay the dish on a bench in a room darkened with dark yellow curtains, and have the length of the dish run from your right to your left hand, as you stand facing it.

“In preparing to lay the sheet on the bath, first turn up the four corners of the sheet of paper to be sensitized at about one-eighth of an inch from the edge, so that you can readily lift it from the bath without having your fingers come in contact with the solution. I also, especially when the paper is dry, gently draw my thumb-nail along the sides of the back of the paper, at about one-quarter of an inch from the edge, being careful in doing so not to crack or break the albumen. This is done so that the sides of the paper will curve evenly in the silvering, and there will not be any sharp angles to it, causing it to sink below the surface, and the solution to flow upon the back of the sheet, thus spoiling the paper.

“*Remark.*—The sheet of albumen paper as it lies before you in the drawer is supposed to be back up, and consequently albumen side down.

“Take up the upper right-hand corner of the sheet (the length of it should run from your right to your left hand) with the right hand, and the lower left-hand corner with your left hand, and let the sheet assume a curved position, the right hand being highest. Lay the lower left-hand corner of the sheet (which you have hold of with the thumb and forefinger of the left hand) on the upper part of the dish, midway between the right and left-hand corners, keeping hold of the turned-up corner while it is there, for the purpose of guiding the corner to its proper place in the dish. As you hold the sheet at present, the upper right-hand corner is up in the air, being held there with the right hand.

“Now draw the corner that is on the solution gently towards the lower left-hand corner of the dish, and at the same time slowly lower the paper on the bath with the right hand, so that by the time the lower left-hand corner of the paper reaches its proper place, the whole of the sheet will be lying in the solution.

“The drawing of the paper towards you drives the bubbles that may be on the bath before the sheet, so that when the sheet is all on the bath the bubbles, if there are any, will be along the edges of and beyond the paper. A slight tap on the back of the paper may be necessary, but that is all.

“While drawing the corner towards you, and lowering the others, be careful that you do not dip the edges of the sides of the paper below the surface of the solution.

“If there should be a few drops of the solution on the back of the sheet while on the bath, they should immediately be blotted off to dryness with white blotting-paper.

“Frequently when the sheet is first placed on the bath, especially during the cold weather, the edges of the paper will curl over. This is a frequent occurrence at all times of the year, where the albumen paper has been for a long time albumenized. Breathing gently (not blowing) will

immediately flatten it. The principal reason why this occurs is because the paper is too dry, as the moist air of the breath plainly proves, and hence a remedy shows itself: keep the paper in a very moist place for a day before sensitizing it.

“After the paper has been silvered long enough, it is then to be raised from the bath. Take hold of the lower left-hand corner with the left hand, and slowly raise the paper until the upper left-hand corner can be caught hold of and held with the right hand. Keep slowly raising the sheet until all the corners are off, and then let the few drops drain off that corner which was placed on the bath last.

“Hang the paper in a dark closet to dry, having that corner the lowest from which the solution was drained off into the bath. Use a spring nipper to suspend the paper by while drying, or hang it on poles, the sheets being placed diagonally, albumen side up, the pole running from corner to corner under the middle of the sheet. This last method prevents the solution from draining to one end of the sheet, as it will do when hung at full length, unless the surplus be removed by one of the methods hereafter described. An even coat of the solution is thus given to the paper, so that all parts of it will print alike. The bath should be stirred every time a sheet of paper has been removed from it.

“It is an excellent plan to draw the sheet of paper, upon removing it from the bath, across a glass rod [see fig.],

or if the edge of the dish is even, then over that, so as to leave the superfluous solution in the bath. I am very much in favour of using blotting-paper for the purpose of blotting the paper as it leaves the bath, and then give the final drying to the paper by artificial heat.

“After the bath has been standing for some time without being in use, there will be a reddish scum on the surface of it, which should be removed with strips of white bibulous paper before another sheet is floated.

“The time for floating the paper depends upon the strength of the bath, the temperature of both the bath and weather, the brand of paper used, and the class of negatives that are to be printed. As a general thing, the paper is floated from twenty to sixty seconds in the summer, while in winter it is floated from forty-five seconds to one minute and three-quarters.

“There are so many local things to be taken into consideration that it is almost impossible to state exactly as to how long the paper will have to be floated, and the beginner will have to make this his constant study, to learn the exact number of seconds necessary.

“The double albumenized paper should be silvered a much longer time than the single, and to prevent cracking of the film the paper should be damp before handling it for floating, and the finished prints, after washing, should be kept wet until mounted.

“When the bath is not in use, and is in the silvering dish, it should always be covered up.

“Pour the bath back into the bottle every night, wash the dish out thoroughly, saving the first two washings, and, until again wanted, set it away, bottom upwards, on a shelf covered with clean paper.”

LITERARY.—*Once a Week* begins a new lease of life on September 5th. It is to be altered in size and appearance, illustrated, and made to occupy the vacant ground awaiting a tenant; for though we have several comic and satirical papers, we have no magazine professedly humorous, and giving novels and sketches of the Lover, Lever, Cockton, or Smedley school.

## AIDS TO PROTECTION OF ART COPYRIGHT.

A LEGAL remedy, it has been said, is open to every man who is robbed or wronged; and so also, it has been rejoined, is the London Tavern. The truth is, a legal remedy, even for a wrong which definitely contravenes the law, is only available to him who has not only money in his purse, but has also leisure to pursue his remedy. One of the irritating forms of wrong to which the photographer is subject is frequent production of unauthorized copies of his work, for which neither remuneration nor acknowledgment is received. Where the piracy to which the photographer is subject is sufficiently serious to cause heavy loss, it may be worth while to invoke the troublesome remedy which the law provides: we say troublesome, because any kind of legal proceedings are inevitably troublesome, and full of anxiety to all who have not purchased familiarity by dire experience. But an especially annoying form of piracy is that to which the best photographers are most subject, namely, the use of their work as copies for the engraver or publisher of illustrated journals, who frequently fails even to pay the poor compliment of acknowledging the source to which he is indebted.

We have before us a prospectus of a company which proposes to supply a remedy for these evils. The "Illustration Company," the initiation of which, we believe, due to Mr. Henry Blackburn, a gentleman who has been considerably interested in the question of art copyright, undertakes to do for artists and photographers something similar to that which the Dramatic Authors' Society does for dramatic writers. It offers to all its members a much readier facility than they individually secure for obtaining recognition and remuneration for the use, for purposes of illustration, of copyright pictures; and whilst it affords to publishers a ready opportunity of acquiring familiarity with works available for their purpose, it removes any temptation to ignore the origin of such works, or make piratical use of them. In many cases photographs are employed by publishers without acknowledgment or payment, because some doubt may exist as to the legitimate recipient of such honorarium, and it is easier to ignore the claim than to find the claimant. The proposed registry will remove all difficulties of this kind, and whilst the establishment of a moderate scale of fees for use of copyright will tend to secure due regard for an author's rights, the extended and systematic payment of small fees may prove lucrative to the photographer. In any case, the scheme is a promising one, and well worthy of the attention of photographers.

The projected plan is very simple. A central registry of copyright pictures available for engraving is to be, or has been, established, where examples and lists of such works will be kept. Publishers desirous of producing such works for illustration in any form will receive a written permission on specific terms to make use of the pictures in question; quarterly accounts and the fees due being rendered to the author of the picture, with a deduction of ten per cent. for working expenses. Nothing could be more simple, nothing more desirable.

## SOCIAL GATHERINGS AMONGST PHOTOGRAPHERS.

It is a note-worthy fact that the two most active, and efficient, and peaceful photographic societies at the present time in existence are distinguished by a more essentially social relation than any other of the existing societies. We refer to the South London Society and the Edinburgh Society. For enduring vitality, activity, maintenance of interest, and absence of serious feuds or misunderstandings, we suppose the two societies named are not surpassed by any other. And, coincident with these qualities, may be noted the fact that both are in the habit of holding meetings in which social enjoyments form a pleasant feature of the gatherings.

The South London Society has for some time past had an annual dinner in winter, and out-door meeting and social re-union in summer; and its genial and esteemed president has for years past annually invited the members to a festive meeting at his house. On Saturday last a new feature characterized the annual out-door meeting, which was held at Kingston-on-Thames. On this occasion Mr. Samuel Fry invited the members to visit the new studio he recently described, and his landscape studio just finished.\* In the pleasant garden a *marquée* was erected, and an excellent cold collation provided for the members. This was but the prelude to a delightful evening, in which music, conversation, examination of pictures, and varied refreshment were combined, the graceful and kindly hospitality of Mr. Fry and Mrs. Fry pervading and leavening the whole proceedings. In response to the health proposed by the rev. president of the society, Mr. Fry incidentally remarked that it was his aim to set the ball a-rolling. And it is to this point our remarks are chiefly directed. As a simple matter of kindly suggestion, not as ostentatiously setting an example, Mr. Fry expressed a hope that similar meetings would become more common amongst photographers; and every one who has been present at any of them must echo the wish. How much good they might effect, and how much evil they might avert, it is impossible to say. The "parent society," which has just—finally, we hope—got through a series of troubles and convulsions, might possibly have escaped them all, if more personal intimacy and *esprit de corps* had subsisted amongst the members, and the shock which has weakened the strength and wasted the time of the society need never have been suffered; for whatever of constitutional imperfection might exist to give colour to the demands for change, it was to petty personal jealousies and rancours the origin of the agitation was solely due. Not simply in averting such evils would more friendly intercourse be valuable: there are many points of mutual professional advantage which might be aided in the informal intercourse which such occasions facilitate. It does not require argument, however, to enforce a point of this kind. It is enough to say that such re-unions are very pleasant; and that suggestion will probably be sufficient to secure for them extended consideration.

\* A description of this landscape studio is in type, and will appear in our next.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE forty-fourth annual meeting of the British Association for the Advancement of Science, held this year at Belfast, under the presidency of Professor Tyndall, F.R.S., has just concluded. The meeting has not been one of the most successful of those held by the Association. The usual soirées, excursions, and sectional meetings have been held; the usual lionizing of one or two distinguished visitors; the usual flutter of excitement in relation to the papers on educational and social questions by ladies. But the meeting marks no special advance in science, no announcement of any discovery, no important practical step gained. The president's address issued in general disappointment. It was naturally expected that the opening address of the annual meeting of the parliament of science would have contained some brilliant exposition of the progress and present position of those branches of science with which the name of Tyndall is associated, if not of the recent advance of science generally. Nothing of the kind, however, entered into the presidential address. It consisted rather of a discourse on teleology—lengthy, superficial, nebulous, eloquent—more closely bordering on philosophy than science. It does not enter into our province in these columns to examine or criticise such an address; but we cannot avoid referring to the strange irony which seems involved in the fact that the inaugural address at an association for the advancement of science should intimate that the final outcome of the study of science was identical in its fundamental ideas with the doctrines of Democritus, Epicurus, and Lucretius. In seeking for the origin of life, force, thought, Professor Tyndall finds all in matter. Lucretius held that matter was eternal, that its ultimate form was indivisible atoms, and that the "mechanical shock" of these atoms was the all-sufficient cause of the universe and all it contains. Professor Tyndall, abandoning (to use his own words) all disguise, confesses that, prolonging his vision backward across the boundary of the experimental evidence, he discerns in matter "the promise and potency of every form and quality of life." But he admits the existence of an "insoluble mystery" in the evolution of life, and thinks that the admission of this mystery saves him from the imputation of "very rank materialism." This presentation of "vacant chaff, well meant, for grain," startled many, depressed more, and left a general feeling of surprise and disappointment.

Papers of photographic interest have not been numerous, nothing distinctly relating to photography except the papers of Col. Wortley and Captain Abney,\* which appear on another page, having been read. Photography, however, is constantly referred to incidentally as aiding in many branches of science. Photographic illustrations of various matters abound. In the geographical section we learn of its value in aiding the spread of accurate knowledge, especially in multiplying maps and charts in various sizes. Its value in doing this without any error in scale or any distortion that can be detected by the most rigid examination, was first proved, we are told, to be "practicable, and was adopted, in the Ordnance Survey Department in 1854 by Major-General Sir Henry James, for the purpose of facilitating the publication of the Government maps of the United Kingdom on the various scales. Since that date the necessity of rapidly producing, multiplying, enlarging, and reducing maps has tended towards the development of various photographic processes which have been brought to such a high state of perfection. During the last five years photograph negatives on glass covering an area of 10,071 square feet of silver prints were prepared and used in the various stages of the survey. An area of 939 square feet of the negatives was also used in producing 13,595 maps on various scales by the photo-zincographic process, which

was also introduced by Major-General Sir Henry James. It was by similar processes that the Germans were enabled to provide the enormous number of copies of the various sheets of the map of France required during the war of 1870-1." Of its value in a somewhat similar direction details were given by Lieut. Chernside, in his account of his experiences in arctic photography.

Bearing on the science of light, Professor Roscoe's description of a new actinometric instrument was interesting. It was described as an automatic instrument for measuring the chemical action of light. It consists of a clock, attached to the minute hand of which is a wheel with platinum points at different distances along the periphery; as these points touch a platinum tipped wire, which rests upon the wheel, a connection is effected by means of which a galvanic current puts in motion a cylinder. Round this cylinder is rolled sensitive paper, exposed through a disc in an insulator to the action of the light. The paper exposed to this disc is blackened by the light, and as the cylinder revolves is carried away and preserved for future observation. The instrument thus takes incessant observations, hour after hour, and day after day, without the work of a single attendant except to wind the clock. It is already in work at Kew, and will possibly be shortly adopted throughout the meteorological observatories of Russia. Its importance outside photography may be recognized when the fact mentioned by the Professor is recollected, that we are so affected by the varieties of the chemical action that the eleven year periods of the sun spots correspond to the violence of Eastern tornados and to the good vintage years of Europe.

ROYAL CORNWALL POLYTECHNIC EXHIBITION.

[FROM OUR OWN CORRESPONDENT.]

THE forty-second exhibition of the Royal Cornwall Polytechnic Society, which was opened on Tuesday last, was of a mediocre character; and in no department was it more manifest than in that which may be called our own.

Exhibits and exhibitors showed a considerable falling off from previous years. This may be ascribed to several causes: the repeated changes in the executive, the want of publicity in regard to the exhibition—no announcement, either by advertisement or paragraph, appeared in the NEWS, as in former years—and the re-imposition of the rule which precludes metallists of the two previous exhibitions from receiving the same award at the current one, a change from which the exhibition most inevitably and righteously suffers.

Mr. W. D. Saunderson, of Manchester, shows five 18 x 22 pictures of Welsh scenery; the best of which, as well as the best of the whole of the large pictures, "At Aberglaslyn," is well worthy of the first silver medal awarded to it. The other pictures by this exhibitor are very ambitious in the extent of country they represent, and although, no doubt, interesting of that which they portray, yet of necessity somewhat tame and flat.

Messrs. Hudson and Purnell, of Ventnor, Isle of Wight, are again exhibitors of the same size views of their locality, and obtain a first silver medal for their "Crab and Lobster," which would, perhaps, have been more appropriate if appended to their "Cascade, Shanklin Chine."

Messrs. Alfred and John Bool have five of the same size pictures, in what may be termed their peculiar style—very sunny, but not particularly sharp. "On the River Wey" is certainly the best, and rewarded with a second silver medal, and a purchaser.

Mr. Reuben Mitchell's two pictures have considerable manipulative skill, as well as choice of subject, and obtain a first bronze medal; the same award being given to the enamels of Mr. W. J. Watson, of Hull.

Mr. Cocking's pictures are scarcely equal to his exhibits

\* Promised copy of Captain Abney's paper on Photography in Connection with the Transit of Venus had not reached us when we went to press.—Ed.

of previous years. An enlarged portrait in carbon, finished in water colours by Mr. Bennett Lowe, is yet under judgment.

In the amateur department there are only three exhibitors: Mr. F. Beasley, jun., with sixteen 10×12; Mr. John H. Morgan, of Clifton, with twelve 10×12; and Mr. W. J. A. Grant, with a frame of five cabinet views.

Mr. Beasley's pictures are not so pretentious in size as the professionals', yet what they so lack they make up in point of quality, in which they may be deemed superior. Water, which hitherto has been the *bête noir* of photographers, seems to be under perfect command of this gentleman, as may be particularly instanced in the perfect rendering of it in a "View at Streatley." A first bronze medal is certainly not sufficient acknowledgment of the value of this fine series of pictures; and here it may be remarked, that on each of this exhibitor's pictures is a note stating the process (Fothergill), the number of days between preparation and exposure, and also between exposure and development. If all exhibitors were to do the same, and attend the make of collodion and nature of lens, they would make their contributions more valuable.

Mr. Morgan's series are all by wet collodion, and are not over-rated by the award of a first bronze medal. Where all are good it is hard to choose, but preference must be given to his water scenes, particularly "The Mill Dam;" one hardly knows which to admire most—the quiet liquidity of the pool, or the slender cascades trickling over the dam.

A good word must be given to Mr. Grant's frame; the contents, though the smallest in size of any, are perfect gems.

### THE STATUS OF PHOTOGRAPHY.

BY R. W. ALDRIDGE.

I ALWAYS feel a pleasure in reading any communication with Mr. Bovey's name attached to it. A mixture of practical sense and gentlemanly feeling is sure to pervade the letter. Were all photographers to think and act in the same spirit, I am convinced there would be no reason to complain of the unsatisfactory view of our art taken by the general public. That such an impression does prevail in the outside world I have only too good reason to know from personal experience; more especially from the good-natured expressions of surprise on the part of my friends that an artist should have anything to do with photography. These people have evidently settled the fine art pretensions of photography in a way far from complimentary to the younger sister, and even seem to consider that there is something incompatible between the pursuit as a profession and the ordinary work of an artist. I generally meet such an objection by producing some work in which the artistic element is conspicuous. What, for instance, could be better for such a purpose than the "Stolen Moments" of Hubbard—a small, but, to my thinking, the most perfect, specimen of combination printing that has yet been exhibited?

It seems difficult to give any one satisfactory reason for this very prejudiced view of the case. Doubtless the low prices have something to do with the matter. Probably, if the suggestion made some time since by Mr. Blanchard, that photographs should be charged twenty guineas each, were carried out, it would be better for the art, and for some of its professors. The difficulty, however, lies in getting the public to agree to such a proposition. That the Bohemians of the black art, who waylay us in every suburban road—who choose the Sunday especially to ply their vocation in the streets of Kew or Richmond, at Wormwood Scrubs, and other similar places—that these gentry who cluster together at our watering places, and produce their new horrors of the sea-shore at the rather extravagant price of sixpence each, should give to the world in general an unfavourable impression, is not surprising. These itinerants bear something like the same relation to the skilled photographer

that the organ-grinder has to the musician. The misfortune is, that while these fellows are seen everywhere, the works of our really great masters—the Crawshays, the Blanchards, the Robinsons—are still, I regret to say, seldom seen, and, to the great mass of the people, comparatively unknown. It happens, too, that some of the names most familiar to the public in connection with the art owe their success to a certain mechanical skill, and still more to their aptitude for business, rather than to any high artistic qualities, which in most cases are principally conspicuous by their absence. To publish a number of cartes of clergymen—or, still better, of actresses in their stage 'undress'—is now the shortest road to commercial success. The public, who hear their names most frequently repeated, naturally conclude they are the principal representatives of the art.

There is at the present time, and that, too, by some of our best practitioners, a great complaint of declining patronage, and a probability, from what I hear, that more than one of our once successful men will come to grief this winter. Whether this want of patronage is owing to the low estimate of the art, is, of course, open to question; it seems, however, likely enough. Mr. Bovey has made some suggestions for remedying this untoward position of things; to which I will add a few ideas of my own, drawn principally from analogy with the sister art of painting.

Mr. Bovey thinks we want "some institution where membership would be regarded as the highest seat of honour, whose certificates might be accepted by the outside world as a certain proof of extraordinary skill and intelligence possessed by each legitimate holder. R.A. sets the status of the princes of the artistic world on an unchallenged throne. F.R.P.S. would doubtless set photography on its proper and merited footing." It seems to me that we want an association of our principal photographers with higher aims, and an exhibition of a much more permanent character, than any we have yet had. London is able to support about a dozen picture exhibitions generally open for about three months at a time, and some of them exhibiting twice in the year. Surely there is room in this great metropolis for a photographic exhibition lasting two or three months, if well placed and well advertised. Picture exhibitions are generally found at least to pay their expenses, and in some instances produce a considerable profit to their members.

It may perhaps appear presumptuous to compare any photographic society with the Royal Academy, who have accumulated a large fund from their annual exhibitions, which are supposed to yield some £20,000 yearly as the result of a three months' exhibition, thus enabling them to provide for the gratuitous education of artists; and also for any of their members who, from old age or insufficient patronage, may require such assistance. Not to instance the Royal Academy only, let us descend to lower ground, and take the two water-colour societies: namely, the Society of Water-colour Painters, and the Institute of Water-colour Painters. These both have their galleries in Pall Mall, and it was in the rooms of the elder body that our short exhibition was held last year. These societies have been established many years, and have found their exhibition such a success that both have now a winter and a spring display. Like the Royal Academy, the number of the members is fixed, and, if I remember rightly, at the same number—that is, forty full members and twenty associates. The latter are allowed to exhibit (in the case of the Academy the number of works is limited to eight; in the water-colour societies no restriction is made regarding the numbers), but have no part in the management. It is from this number of associates that the members fill up any vacancies that may occur in their own body. As the success of the society depends entirely upon the excellence of the works exhibited, they naturally select the best men for their members.

I cannot help thinking that a body composed of our best photographers, with a proper "local habitation and a name," would help to give a dignity to our wonderful

art that is now painfully wanting. A royal charter might be a subject for future consideration. It seems to me that the art claims of the profession would be much more readily admitted if the president of the Royal Academy, or some well known artist—Mr. Millais, for example—could be induced to take the presidency. At any rate, the headquarters of the society and its exhibitions must be in London. We have peripatetics enough already; we do not want a society to follow in their footsteps.

Whether photography has yet reached a point at which it is desirable that such a society should be founded is, of course, a question for consideration. The money value attached by artists to membership may be gathered from a fact within my own experience. Some time since I was speaking to a painter whose son had just been elected an associate of one of the water-colour societies mentioned, when he observed that it was worth a thousand pounds to him. I remembered that about a dozen years before I had been pressed by two friends, who were members, to join their society; being at the time desirous to turn more of my time to painting in oil, I had declined, but could not, now that I heard the value attached to the connection, forbear smiling at the idea of having lost £1,000 in that way. I enquired his idea of the value of the R.A. attached to the name of an artist, with its privileges. "Oh! was the answer, say £5,000." This was of course a fancy estimate. It must, however, be remembered that, if required, a member is entitled to a pension of something like £200 a year. The profession of an artist is now one of acknowledged respectability, and its members are generally received as gentlemen. That it was not always so, one or two extracts, principally from Beechey's Life of Sir J. Reynolds, the first president of the Royal Academy (established in 1769), will serve to show. I add one or two more in connection with the progress of the Royal Academy that seem to me interesting, as illustrating the position of the photographic body. It will be seen that the *status of artists* in this country, prior to the foundation of the Academy, was certainly capable of being improved:—"The works of English artists," observes Mr. Farington, "had been hitherto seen only by a few, and the greater part of the community knew absolutely nothing of what was passing in the arts. Private collections were then inaccessible, and there were no public ones, nor any casual display of the productions of genius, except what the ordinary sales by auction occasionally afforded." "The history of our exhibition," Farington continues, "affords the strongest evidence of their impressive effect upon public taste. At their commencement, though men of enlightened minds could distinguish and appreciate what was excellent, the admiration of the many was confined to subjects either gross or puerile, and commonly to the meanest efforts of intellect; whereas at this time the whole train of subjects most popular in the earlier exhibitions have disappeared. The loaf and cheese that could provoke hunger, the cat and canary-bird, and the dead mackerel on a deal board, have long ceased to produce astonishment and delight; while truth of imitation now finds innumerable admirers, though combined with the high qualities of beauty, grandeur, and taste. To our public exhibitions, and to arrangements that followed in consequence of their introduction, this change must be chiefly attributed." One more extract, and I have done. "Such an example [that of Sir J. Reynolds] at the head of the arts," continues Mr. Farington, "had the happiest effect upon the members of the profession. No class of society manifested more speedy improvement than the body of artists. In the example set by Sir Joshua Reynolds, he was supported by some of his contemporaries who were highly respected for the propriety of their conduct and gentlemanly deportment. So striking was the change, that a much-esteemed artist, far advanced in life, being a few years since at a dinner-table surrounded by men of his own profession, recollecting those of former times, remarked the great difference in their manners, adding, 'I now see only gentlemen before me.'"

A PRACTICAL SUGGESTION FOR STEREO-LANDSCAPE NEGATIVES.

BY JOHN C. BROWNE.\*

THE making of stereoscopic pictures is one of the most lucrative departments of photography, and the number and variety of subjects everywhere obtainable of the "wonders of the world," together with the vast assortment of historical views and local bits of interest, make a collection of endless extent and beauty.

If anything can lay claim to popularizing photography, it has been the discovery of the principle of the stereoscope, and the fund of information, as well as pleasure, gained by examining pictures through its magic lenses.

Various changes and improvements have marked the advance in the construction of camera boxes and lenses suitable for making stereoscopic negatives. From the original idea applied to photography, of a clumsy box and single lens, ill adapted for the purpose, arranged to turn on a table at the required angle, and necessitating two entirely separate exposures to produce a single stereoscopic picture, what a wonderful change to the elaborately constructed binocular instruments of the present day, embracing all that is necessary for rapid adjustment, portability, and first-class results.

The size of glass has altered considerably. From a plate less than three by seven inches, it has been enlarged to five by eight, and with good reason. Such a plate allows a picture to be cut from it larger than the former size, with pleasing effect, provided that the extra amount of subject is not added to the width of the picture, but to the top or bottom, otherwise the distance from the middle of each picture will be too great for proper stereoscopic effect. This size is very popular in America, being almost universally used, even if the prints are put upon three and a-half by seven inch mounting cards.

While the author deprecates the constant changing of the size of picture, as adding much expense and unavailable material to the photographer's outfit, still there are advantages in a larger size of glass eminently useful and practical. Instead of a five by eight camera box, none are made with a holder capable of taking a plate eight by ten, with one pair of stereoscopic lenses arranged in the usual manner. The holder can be adjusted to expose the upper part of the plate, the lenses covered after exposure, then the lower portion can be exposed, by a readjustment of the holder, by placing it in the position of the first. Two stereoscopic negatives of the same subject may be obtained without altering the position of the camera. This may appear, at first sight, of but little importance, but it has the double advantage of two chances to obtain a perfect picture, and, should both be successful, a duplicate negative with one manipulation. Applied to gallery work, this is a very old idea, having been duly secured by patent, or application to that effect; but as an assistant to the landscape photographer, I have never seen a notice of it in print. During last summer my attention was drawn to the practical use of this arrangement in the hands of Mr. J. A. Graves, who has so well portrayed the charming scenery of the Delaware Water Gap. Doubtless it has occurred to many photographers that a camera of similar construction would be useful, but we can learn of but few that have adopted it for landscape purposes.

Notes and Queries.

THE FOCUSING CONUNDRUM.

SIR,—The conundrum which "O. G. R." puts for solution involves an interesting and knotty point. Strict accuracy would demand that the camera and figure should not be moved in any way, but remain where they are, the focussing alone being modified. The figure, being out of focus by being further off,

\* *Photographic Mosaics.*

should of course have the focus shortened to bring it into good definition. But then comes another difficulty. By shortening the focus the size of the figure will be slightly reduced (as for true perspective it should be), and in double printing it will not quite fill the space of the blurred image; whilst if the camera were moved slightly to bring the figure into focus, the image would be slightly larger than true perspective would demand, but would fill the space of the blurred image.

On the whole, I should prefer not to move the camera, but to bring the figure into focus, accepting the infinitesimal reduction in size, and cut my mask as small as possible for the double printing. If a trace of the blurred edge of the out-of-focus figure were not quite masked out it would not seriously matter.

X. Y. Z.

The figure out of focus was, of course, taken on the same plane as the foreground figures, and no doubt too large, but unappreciably so. Now, if I screw-up or shorten the camera slightly, I get him easily in focus, but on another plane—more distant, and too small to fit the original Mr. Blurr. Therefore it would be better to leave the camera untouched as to lengthening or shortening, but push it nearer to the object, until it became softly in focus, and then the head would fit the body, or the lower part, seen under the table, would remain in the original groove.

Q. E. D.

SIR,—In answer to the Photographic conundrum in last NEWS, I have to say that if "O. G. R." shortened the focus of the lens for the second plate, he would get gent. No. 3 too small to supply his place on plate No 1. By moving the camera nearer he would obtain an image a little too large for true perspective, but he would have no trouble to print it in place of the first out-of-focus figure. The best plan would have been to leave No. 3 out of the first group, then to shorten the focus, and do No. 3 alone behind the table.

SPOTTED-OUT.

SIR,—Your correspondent "O. G. R." is almost as noted for his love of a joke as for his dark deeds with the camera. I cannot help thinking, therefore, that Mr. Rej—I beg his pardon: "O. G. R."—is making fun of us in the question he puts. How can he get No. 3 into focus, either by shortening the camera or by pushing it forward, without throwing the other figures out of focus? I should cut the knot by moving No. 3.

R. A.

#### TEXTURE OF HAIR IN ENLARGEMENTS.

SIR,—“Artist” does not tell us how the fine, flossy, glossy beard in good focus was enlarged so that it became like a coarse rope. I have seen enlargements with this harsh rope-like hair, and I have seen some without. I fancy the objectionable coarseness is generally obtained when a transparency from the negative is taken by the ordinary wet process, and an enlarged negative taken from that. It seems natural that the crystalline deposit produced by iron development, when enlarged, should look coarse. Then I believe opticians state that there is some blurring in the transparency caused by the diffraction of the light passing through the fine spaces of the negative when camera printing is employed. Mr. Edwards states that no such coarseness of hair arises when a good albumen transparency is used, and, if I am not mistaken, he once promised, at some future time, to explain the *rationale* of this. Has he ever done so? If not, would not this be a good time to make the explanation?

ANOTHER ARTIST.

#### PRELIMINARY COATINGS OF ALBUMEN.

SIR,—Like "R. M. S.," I have been unsuccessful in the use of an albumen coating in the wet process. I have found the albumen troublesome to keep, troublesome to apply, and of uncertain value. I have generally used it made with one egg to ten ounces of water, with a little ammonia added. I think it is possible that further light might be thrown on the subject if it were discussed in your puzzle column of "Notes and Queries."—Yours obediently,

A LAZY AMATEUR.

[As the letter of the following correspondent really touches the question of the "Lazy Amateur," we place it as an answer in the column of the "Notes and Queries."—ED.]

DEAR SIR,—My experience with the preliminary coating of albumen is of only short duration, but it is such that, so long as

I have negatives to take, I believe I shall continue it. I use the white of one egg to the pint of water (possibly a weaker solution may be better, as you suggest) with a few drops of ammonia. Having thoroughly washed the plates, while still wet I place (say) half a dozen quarter-plates to drain at one corner, so as to have only sufficient moisture to allow the albumen to run over the plate. Holding the plate with the finger and thumb perfectly dry, I pour the solution in the same way as in collodionizing, and stand to dry on blotting paper, or damp cloth, and hitherto have found no detriment to the bath.

VERNUM SAP.

#### A DEVELOPING QUERY.

In developing a plate, you should, by chance or awkwardness cause a little *island* to be untouched by the developer (of course, it ought never to happen), then pour on it after the formation, as much, and as long as you like, the part of the picture at that spot refuses to come out. I am not surprised that the boundaries of that spot "island" will always remain; but why has "d. spot" ceased to move, and open its pores like the other part of the plate?

ENQUIRER.

#### PHOTOGRAPHING FLOWERS.

SIR,—You have often helped me out of difficulties: will any contributor to your PHOTOGRAPHIC NEWS tell a lady how to photograph groups of flowers? When I expose the proper time for the flowers, the leaves, and stalks, and buds are under-exposed. I have tried with paraffine oil, and with gum, to make transparent paper to gum on the back of the negative, with the idea of working up the leaves in pencil, but the paper loses its transparency after a few hours. I tried wetting the leaves, and also varnishing them, but it did not succeed in making them more sensitive to light.

A LADY.

### Correspondence.

#### A CHEAP STILL.

DEAR SIR,—I send you the details of a still which I use, and which is cheap.

A is a tin can filled with water, which is put on a common fire or gas stove. B is a stone or tin bottle which

is put into a saucepan (C) filled with cold water. D is a thin pipe about a quarter of an inch diameter, which is passed through the cork of A; the other end is put loosely into the bottle (B) nearly to the bottom.—I remain, your obedient servant,

C. I. E.

#### DR. VOGEL'S DISCOVERY IN PRACTICE.

SIR,—There will be some hopes now to photograph a sunflower after reading Dr. Vogel's discovery. Last year I tried many times to photograph some fine sun-flowers—a fine emblem of photography—but was not very successful. I tried letting the sunshine on them through a blue glass, but there was no improvement upon the sunlit one; it was good enough to draw from, but not good enough as a photograph, except in the highest bends of light.

O. G. R.

#### MR. TILLEY'S DOUBLE PRINTING SECRET.

SIR,—Mr. Tilley's generosity in allowing photographers six months for speculation, experiment, and suggestion in relation to his method of double printing will be found in

many cases rather tantalizing, I fear, as "hope deferred maketh the heart sick," and damps the ardour of enthusiasm. I fear that most of the proposals have been rather wide of the mark. I notice that in order to solve the method of working *without* cut-out masks proposed by Mr. Tilley, various correspondents propose a method *with* cut-out masks. Mr. Werge's proposition in a contemporary, of using the powder and bichromate process, in a manner somewhat similar to that already proposed in your columns, will, I fear, be found defective in practice. He proposes to take the portrait with a plain dark background screen, so that in the negative the background will be somewhat transparent. He would then coat the face of the negative with the sensitive dextrine solution, and print under a landscape negative, and finally develop with plumbago, taking care to avoid the figure in applying the blacklead. He says that the film of bichromated dextrine will need no washing. It is here I am at issue with Mr. Werge. I tried your suggestion, some time ago, of improving a thin negative by applying the powder process at the back, and proceeded to print without washing, thinking the thin yellow film would only slightly retard printing; but I found it became brown and opaque under the action of light, and not only retarded, but altered, the whole conditions of light and shade.

The plan which Mr. Burgess proposed some time ago, and of which Mr. Werge's proposal appears to be a modification, seems to me most nearly to meet Mr. Tilley's conditions. He coated the varnished negative with collodio-chloride, painted out the figure with indian-ink, printed, and fixed. The indian-ink was washed off in the process of fixing and washing, and the negative had a landscape background produced on it, whilst the figure remained untouched.—Yours very truly,  
W.

#### HEALTH OF PHOTOGRAPHERS.

SIR,—One word as to health. For some two or three years my health was failing, and my medical adviser recommended me Turkish baths; and from twelve months' experience I may speak somewhat positively as to their beneficial effects. No doubt from respiration, as well as through the pores, we constantly imbibe more or less of chemicals into the system, which ordinary bathing, warm baths, or washing will never remove, but which Turkish baths, from their peculiar nature, will. I know the medical profession, as a rule, do not countenance them, but I know the value of them personally, and am desirous, as far as possible, to advocate them amongst photographers. I may say I have accomplished more individually the last twelve months than in the three years previously; in fact, I was brought so low, from nervous exhaustion, that I was necessitated to leave home. Hoping you will give this some advocacy in your valuable paper, I remain, dear sir, yours

VERBUM SAP.

#### Proceedings of Societies.

##### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE August out-door meeting of this society took place on Friday, the 21st instant, when, notwithstanding that so many are at this season out of town, a good number turned up at the Waverley station at seven o'clock; and as several members were picked up at the various wayside stations *en route*, fully the average number reached East Linton a little after eight o'clock, where, in Sharp's Railway Hotel, ample justice was done to a substantial breakfast.

The foundation having thus been laid, and all necessary information as to the best route to the various places proposed to be visited having been obtained, the party started in suitable conveyances, determined to make the best of the day, which, photographically, was all that could be desired. The first point of interest was Hailes Castle—an interesting relic of ancient times, but not of much value to the photographer in search of the picturesque, and so only three cameras were brought to bear on it.

We need hardly say that those who did not photograph were not idle. Fun and frolic were the order of the day, and especially prominent were a few who seemed strong in punning powers. The first hit in that direction was made by Mr. Stenhouse; and as it was really good—which is more than can be said of such attempts generally—we give our readers the benefit of it. The members were walking single file along a narrow pathway leading from the ruin, when he, slightly altering the name "Cameron," quoted in musical chant the line of the well-known song—"Tis the march of the camera men."

The next halt was made at Whittinghame, the residence of Mr. Balfour, a grand old house standing in the midst of a gloriously-wooded landscape. Here a few pictures were taken, when it was declared time for luncheon, which was very much enjoyed under the grateful shade of some fine old trees, after which the order was given to proceed to Biel House, one of the residences of Mr. Nesbit Hamilton, and, in the opinion of the leader of the party, the best bit in the route.

On the way the party came in sight of a neat tiled cottage close beside a quaint old bridge, and at the end of a beautifully-lying and well-kept garden; what, however, attracted their attention was, not the house or garden, but a large glass house at the opposite end of the garden, bearing unmistakable evidence of having been built for photographic purposes. Why a photographer should settle down in a locality miles from even the smallest village, and almost as much from his nearest neighbour, was a puzzle which they at once resolved to solve, and so the two secretaries were despatched as a deputation. The place they found was called Lint Mills, and the owner was a Mr. Nisbet, who, according to the evidence of a nice-looking young woman, the only person about the place, "did a very good trade amongst the people round about." Mr. Nisbet himself was from home, but she produced the key, and asked them to go and look at the studio and pictures. Both were in their way first-rate, the latter quite equal to the average productions of his brethren of even the largest cities. The girl, apparently proud of her uncle's abilities, then invited them to examine his workshop, where they found that he combined the profession of carver in wood with that of photographer; and although there were no specimens of his work in this department to be seen, there were a number of drawings from which carvings had been made which showed that Mr. Nisbet is undoubtedly a man of genius, who enjoys the quiet of a country life, and who possesses the ability to make it pay.

Biel House was reached shortly afterwards, and here the first hitch occurred. The family were from home, the factor was in Haddington, and the gardener, the only other man who could give permission to visit the house and grounds, was away at a funeral. It was, however, quietly hinted that the doors and gates were open, and that "there is nae body at hame to hinder ye to take leave." The hint was of course taken, and the party were well rewarded for their courage. Biel House is really one of the most lovely places in Scotland, and admirably adapted for the work of the camera, including, as it does, a fine old house in the middle of a magnificent fancy garden, surrounded by a densely-wooded park, through which runs a fine stream spanned by several bridges. In front of the house stands, undoubtedly, the largest, and probably the oldest, cedar in the country, it having been planted in commemoration of the union between England and Scotland. All cameras were soon at work, and kept at it till every plate was exposed, and still it was by one consent agreed that the work had not been half done. Every turn of the road brought some new beauty into view, and made them wish that they had counted their plates by tens instead of units.

At five o'clock the signal was given to constitute an ordinary meeting of the society, and the president took the chair on the top of Biel Bridge. The minutes of the previous meeting were held as read, and Messrs. J. Thompson and Casimir Roques were admitted ordinary members.

This being all the business the meeting was adjourned, and the party drove off on their homeward journey towards East Linton. Here they finished up with the usual tea-dinner, and were just in time to catch the last train for Edinburgh, which they reached at half-past eight, highly delighted with the proceedings of the day.

#### Talk in the Studio.

ALBUMEN PRELIMINARY COATING.—A correspondent says:—"I see in your last that I am not the only one in trouble with the albumen for plates, as my experience causes me to abandon it, and refer to elbow powder; namely, for plates that have

been in use and varnished, I put about eight at a time into an old sensitizing dish (say 10 by 8), and pour over them boiling water; then I take a broken table-knife, sharpened fine like a joiner's chisel, and well shave off all the film, varnish, and then wash under tap; then rub with fine rouge prepared for polishing (sold at three shillings the pound), damp it, and rub the plates; set them to dry; rub off when dry, and they polish as fine as when new. They are the glass called "foreign plate," sold to me by Harvey and Co., Leeds—the best kind of glass made for photographic purposes, and cheap, and I never find one dirty after going through the rouge," &c.

**PHOTOGRAPHING THE INVISIBLE.**—A curious illustration of the slow travelling of ideas, even in the present period of journalistic activity, is just furnished by a paragraph which has appeared during the last week in some of the daily papers, extracted from the *London Medical Record*, being an account of the experiences described just twelve months ago before the British Association at Bradford. The paragraph is as follows:—"Dr. J. H. Gladstone, F.R.S., has called attention to some photographs of fluorescent substances, which the editor of the *Philadelphia Medical and Surgical Reporter* thinks may help to explain the mystery of the so-called spirit photographs of which we have lately heard so much. It appears that the fluorescent substances, such as bisulphate of quinine, or uranium glass, have the power of altering the refrangibility of the violet or chemical rays of light; hence, although paper painted over with bisulphate of quinine will look nearly white, it will appear in photographs as if it were nearly black. Dr. Gladstone has exhibited some photographs of ornamental design traced on white paper with bisulphate of quinine; although the designs were nearly invisible to the eye, in the photographs they were boldly visible. A colourless solution of bisulphate of quinine was placed in one glass, and some ink in another glass; when both glasses were photographed they came out equally black. Dr. Gladstone said that once at the seaside he painted a pattern with bisulphate of quinine upon paper, and took the paper to a photographer to be photographed; he objected, because there was nothing on the paper, but on trying the experiment he found out his error. It was stated that some kinds of varnish possess a similar power of affecting the refrangibility of light."

**MANSSELL'S PHOTOGRAPHIC SKETCHES.**—Mr. Mansell sends us some very charming studies, drawn by an artist whose name is new to us—Mr. Francis Miles—but over whose pencil we linger with never failing delight. In his "Ruth" we have the careful, sadly-thoughtful widow; in "I've been Roaming" we have the mirthful bewitching face of one who is seen at her best in the usual hours of the morning. This method by Mr. Mansell seems to claim a special value as a means of reproducing pencil and crayon sketches of the old and of later masters, and of artists' studies in general. The imitation of the original material of the sketch is perfect; anyone not in the secret would at once imagine he was examining a work produced by the pencil; and this, not merely in the sharper outline, but in the shaded parts, where the graphite tone is even more exactly copied. The effect is, of course, heightened by the employment of matt paper, instead of the usual albumenized surface with its bright gloss.—*Bookseller*

**RAIN WATER IMPURITIES.**—In a recently published work on "Sanitary Arrangements for Dwellings," Mr. Eassie points out the precautions to be adopted in cases where rainfall forms the chief or only source of water supply. Generally it will be found convenient to store rain falling on the roof in an underground tank, formed of brick or concrete, puddled outside with clay and covered inside with Portland cement. But care must be taken that the down spouts conducting the rainfall to the tank do not drain either zinc roofs or lead flats. Even on tile or slate covered roofs, the water will have passed over lead flashings, ridges, hips, and valleys, charging it with a small percentage of lead, but not more than one-twentieth of a grain to the gallon. With a greater proportion than this, water becomes dangerous to use, being more or less poisonous. Since rain acquires certain impurities, even while passing through chemicals or the air, it should always be carefully filtered—before being used for drinking or cooking purposes. In the case of a house supplied with an underground receptacle, filtration could be easily managed, by placing an earth filter on the delivery side of the down spout, at its exit from the tank. An eminent authority on sanitary subjects, Dr. Angus Smith, believes rain water can be so completely filtered through earth as to remove all impurities. Whenever rain water is stored for drinking purposes

the eaves of the roof, troughs, and down spouts should be enamelled, and the supply ought to be carried to the tank through glazed earthenware pipes. This prevents leading, but other deleterious ingredients will still remain. In manufacturing towns, soot, oil, and sulphuric acid form some constituents of rain water. With those facts in view, most people will agree with Mr. Eassie, in his conclusion that "generally speaking, rain water should be excluded from the kitchen," although extremely useful in laundries and conservatories.—*Scientific American*.

## To Correspondents.

- A. WALL.**—Crapiness in collodion is generally caused by the ether and alcohol employed in its manufacture not being sufficiently highly rectified; but the same result may also be brought about by bad manipulation. If, for instance, the plate be immersed in the nitrate bath before the film is fully set, a crapy condition of film will sometimes result. If the collodion be thick or glutinous, the absence of skill in coating the plate, and duly rocking it from side to side, will sometimes produce a crapy appearance. If the fault be in your manipulation you may easily avoid it; but if it be in the collodion there is no remedy but getting it exchanged by the person of whom you obtained it.
- J. E. B.**—Mr. Willis's address is at Scarborough; we do not remember precise details. He does not manufacture paper for the trade; and having freely given the results of his experience to photographers, it is scarcely fair to trouble him further. Each photographer should work out difficulties for himself. At the time when the matter was published the details were discussed in the *PHOTOGRAPHIC NEWS*, and Mr. Willis gave all the information he could through our columns. We cannot answer letters on photographic subjects privately.
- G. WALLIS.**—Various formulae for the lime toning bath have been published in our pages, so that we cannot tell you which you refer. A very simple and good formula consists in using three grains of chloride of lime to two grains of chloride of gold in twelve ounces of water, mixing the solution twenty-four hours before use.
- C. M. M.**—In making enlargements, the position of the lens may, with advantage, be reversed, the front of the lens being turned to the larger image, as it is in portraiture. 2. If you have no use for your No. 4 it will undoubtedly be wise to change it for something which will be of use. We cannot answer photographic queries by post, and as they do not come under our attention until we are writing these answers for the *NEWS*, no time would be gained if we did.
- AN AMATEUR.**—Slug tracks of matt silver on negatives may proceed from various causes, but they chiefly arise from the use of a horny, repellent collodion. The collodion may be modified sometimes by the addition of a few drops to each ounce of distilled water; sometimes by age; and sometimes by adding a little old collodion. Immersing the plate before it is too much set is sometimes a remedy. Be careful to allow the plate to rest on pieces of clean blotting-paper, and keep the inner frames scrupulously clean by constant washing with clean water. Re-dipping the plate in a pure neutral twenty-grain solution of nitrate of silver after exposure is sometimes a remedy.
- J. BRIER, JUN.**—Mr. Gordon is out of England, and has been for some time. When he will return we cannot say. Hence, you will see, we cannot say anything of his intention in relation to his albumen process. You appear to have attained to considerable success in dry plate work. The prints you forward are excellent. Spots are, so far as we know, only to be overcome by especial care in manipulation, especially in filtering solutions. We shall be glad if you will give our readers a synopsis of your experience in dry plate work.
- CUMBERLAND.**—Glucose is grape sugar. It may be obtained of most chemists. 2. Your silver bath containing acetic acid may be used for exciting albumenized paper; but it would have been better without the acid. There is no ready way of removing the acid.
- A LADY.**—The best plan we knew to photograph groups of flowers is to place them in a good light and give a good long exposure with a collodion containing a large proportion of bromide. We place your letter in our column of "Notes and Queries," where it is possible some other experience may be elicited.
- B. L. G.**—There is no patent for an enamel process in force in this country at the present time, so far as we are aware. The general principles of all processes are known and published, but certain details of formulae and manipulation are kept secret. We cannot write private letters on such subjects.
- N. R.**—We do not think that the amorphous albumenized paper can be obtained in this country at present. It was not much in demand, and ceased to be imported.
- A "NOTE ON THE SALTS OF IRON SENSITIVE TO LIGHT,"** by W. H. Watson, in our next.
- Several Correspondents in our next.

## PHOTOGRAPHY IN AND OUT OF THE STUDIO.

## LORD BROUGHAM AND THE INVENTION OF PHOTOGRAPHY—SUCCESSFUL COMMERCIAL PHOTOGRAPHS—PHOTOGRAPHY IN ARTISTOCRATIC CIRCLES.

*Lord Brougham and the Invention of Photography.*—Although, doubtless, Lord Brougham's experiments with light would have caused the subject of depicting images by means of the sun to be more assiduously studied at the close of last century, had they been published to the world, one can scarcely believe that they would have been instrumental in giving us a practical process at an earlier date. In the "Memoirs of Lord Brougham," written by himself, he thinks that, in all probability, photography would have been known to the world much earlier if only a communication which he forwarded to the Royal Society in 1795 had been published *in extenso*. Many of our readers are aware of the allusion made by Lord Brougham to the subject. He says the paper was very courteously received, but Sir Charles Blagden, the secretary, desired parts to be left out in the notes and queries, as belonging rather to the arts than the sciences. "This was unfortunate, because, having observed the effect of a small hole in the window-shutter of a darkened room, when a view is formed on white paper of the external objects, I had suggested that if that view is formed, not on paper, but on ivory rubbed with nitrate of silver, the picture would become permanent; and I have suggested improvements in drawing founded on this fact. Now this is the origin of photography; and had the note containing the suggestion in 1795 appeared, in all probability it would have set others on the examination of the subject, and given us photography half a century earlier than we have had it." Brougham's name, therefore, should certainly be added to those of Wedgwood and Davy and other early investigators of photographic action; but seeing that it is only a suggestion, and no practical result, that is in question, it would scarcely be fair to other more successful experimenters to call Lord Brougham the originator of photography, a position that has recently been claimed for him by the press.

*Successful Commercial Photography.*—The penny paper, the *Figaro Programme*, which has hitherto presented its readers with a *carte-de-visite* portrait produced by the Woodbury process, has found it impossible to give both picture and paper for this moderate amount, and has announced that the price will be double in future. It is to be hoped that when this innovation takes place, the publishers will use a little more care in the selection of the prints. When photographs are bought too cheap, no matter how they are produced, whether by mechanical or sun-printing, there is sure to be a goodly percentage of failure, for photographers cannot afford to make a selection of the better pictures, and supply these only. For a very slight increase of outlay in the production of the portraits, a much better average would be secured, for the printers would then be enabled to supply none but the most perfect copies. Selection is one of the principal points to be attended to, as every photographer knows: you can get a dozen *cartes* for five shillings at one house, and only half that number for the same money elsewhere; but the chances are, both establishments have printed the same number of copies from the negative, only in the latter case but the six best pictures are given you, instead of the whole batch, good and bad. A photographer cannot but gain reputation by supplying quality instead of quantity, and many a studio has gained a high position by sticking to the wholesome rule of never letting mediocre work go out to customers. It is no easy task to obtain a series of pictures all up to the highest standard, but there is never the slightest difficulty in weeding out prints that are really bad,

*Photography in Aristocratic Circles.*—Many of our readers know the Duke of Edinburgh to be an accomplished photographer, an art he acquired on purpose for his tour round the world in H.M.S. *Galatea*. We are now informed that Prince Arthur—or, as he is at present styled, the Duke of Connaught—is a good dry-plate worker, and spends much of his leisure in securing camera pictures. As a portraitist he is also an efficient, most of his models being members of the Royal family, who are never tired of sitting to the illustrious amateur. With such august personages in the ranks, photographers need be under no apprehension of their calling sinking into disrepute, as some of our correspondents have lately feared; in this country, more than any other, is the art adopted as a gentlemanly pursuit, and so high in rank are some of our most skilful amateurs that one of these days we may rather anticipate the profession to be entirely in the hands of the upper ten thousand.

## ON THE MULTIPLICATION OF MAPS AND PLANS IN THE FIELD.

BY CAPT. ABNEY, R.E., F.R.A.S., F.C.S.\*

WE next have to consider the multiplication of photographs. This is highly useful, as at long distances a photograph of an outwork, for instance, can be obtained, and by an ordinary enlarging process the details can be rendered visible without the aid of a telescope. It rarely happens, or could happen, that above thirty or forty copies of a photograph can be required. If only three or four be wanted, the ordinary silver printing process or albumenized paper can be utilized. If more than this number, papyrotypy can be employed. In this case a reversed negative, taken by means of a prism of total reflection placed in front of the lens, is made use of, and the negative printed on the gelatinized paper. As has been happily said, "gelatine, acted upon by light, has a discriminative power of absorption of water;" that is, just in proportion to the intensity of light acting upon it, so is it incapable of absorbing water. And after absorbing water, it has the same discriminative power of taking greasy ink.

Now it will be apparent that after printing a half-tone negative on this paper, and after soaking it in water, it will have the power of taking lithographic ink from a roller with different degrees of intensity. When inked in this manner, and placed in a common printing-press, it is manifest that an impression giving gradations of light and shade can be obtained by bringing ordinary paper in contact with it. The ink having been taken up by the paper, the roller, charged afresh with ink, can be passed over the gelatine, and more impressions pulled. Forty or fifty copies in this way can be obtained, and they are, of course, permanent, the picture being built up in printers' ink.

There is no novelty in this method. It is similar to the heliotype process and other mechanical printing processes; but it has this advantage, that in the latter it is necessary to obtain a solid layer of gelatine on a glass plate. The layer is readily sensitized, by the addition of bichromate of potash, and also resins to give it toughness; whilst the papyrotype paper can be kept in rolls of forty or fifty feet, and sufficient can be sensitized by floating on a bichromate of potash solution, as may be required. In the field it would be hopeless to try to prepare gelatine films on glass, as they require room, and also considerable time to dry. Forty-eight hours is, at least, required before they can be printed from, and the least particle of dust on the surface is fatal to good printing. The sensitized gelatine film only keeps a limited time, varying from a week to a month; whereas the paper is always ready. For the field the papyrotype process answers the purpose required, and has been adopted by the Engineer authorities.

At Chatham for ordinary work—such as illustrations of

reports—we use the heliotype process. A brief outline of it may be useful:—A glass plate is carefully levelled, and a solution of gelatine, chrome alum, bichromate of potash, and milk is poured over it. This is allowed to set, after which it is raised up and allowed to dry. This, as before stated, takes about forty-eight hours. When dry the gelatine film (which is sensitive, owing to bichromate of potash) is stripped off; one side is then hardened by exposure to the sun, and the other is then placed in contact with a negative. When it is judged that sufficient printing has been given it is slightly damped, and made to adhere to a pewter or zinc plate. It is next immersed in water for a quarter of an hour to swell up those parts on which the light has not acted, and also to soak out the bichromate of potash. The gelatine print is then placed on the bed of an ordinary printing-press, and a soft roller charged with greasy ink passed over it. The prints are obtained in the same way as described for papyrotypy. For a depot nothing could be better than this plan, and it has astonished me much that more book illustrations are not done by it. I produce a few samples of the work executed by this method.

The equipment for the field as regards photography consists of a waggon, of which I have a photograph here. It is a dark room in itself, and has all the usual fittings of such. It is furnished with four cameras—two to take 12×10 pictures, and two 8½×6½, and stereoscopic. Both the large cameras are of the bellows form, and expand to such a length that a plan can be enlarged to six times the scale. The battery of lenses is complete, ten being furnished of different focal lengths. They are all non-distorting, and give marginal straight lines. A complete outfit for the smaller cameras is likewise carried; that is, a dark tent carrying chemicals sufficient for three days' work. This requires two men to manipulate. With the smaller camera one man can carry thirty-six dry plates, and must work independently of the waggon, save in the matter of developing his pictures. The same waggon carries sufficient stores for a three months' campaign, every article necessary for the reproduction of plans and prints, as far as photography is concerned, being part of the outfit. The waggon is horsed by two horses, as a rule, though four are laid down for its transport in the field. The full complement of photographers is five, viz., one non-commissioned officer and four Sappers; each of these would have passed through the photographic course at the S. M. E., and have a thorough knowledge of photography in all branches, especially plain work.

The lithographic department is furnished with a waggon similar in all respects. It carries stores estimated to last three months. The size of the press is naturally limited, double-foolscap being the size of stone which it will take. Stones are not much carried, some half-dozen being all that are thought necessary. It carries, however, three dozen zinc plates for zincography. Provision is made for night work, and, in consequence, it is estimated that two non-commissioned officers and four men would be the staff required for work.

The printing waggon for typography and papyrotype work in half-tone is also of the same pattern, and is supplied similarly with three months' stores. Two compositors (Sappers) and one non-commissioned officer are the authorized number of men attached for this duty.

The War-Office authorities have decided that each of these waggons shall be attached to the Telegraph Troop of Royal Engineers. Thus the whole branch of the intelligence department will be combined in one. As there will be one telegraph troop to each division of the army, it follows that every general commanding will be in an independent position as regards his collection and distribution of useful intelligence.

Thus the telegraph troop will connect his division with headquarters by telegraph. They will multiply his plans, photograph any point which may be of interest or use

during the operations, and print his orders for distribution to the subordinate commanding officers. This last point is one well worthy of attention. In old days, when each regiment had to copy out the the general orders from one order book, it was often the small hours in the morning before a regiment knew what time it would have to start. This worry is one well-known even in peace time to those who used to serve at Aldershot or in the earlier manoeuvres. I need hardly point out the necessity that existed of remedying it as far as possible.

We also have a mountain photographic equipment, which can be carried on the backs of three mules, weighing in all about 300 pounds. The size of the plates that can be used for photographs is 12×10. There is everything in it for the reproduction of plans for papyrotype transfers; but as yet we have no mountain equipment for lithography, as there are certain difficulties in the way which are not as yet quite overcome. We have, however, a mountain telegraph and typographical printing equipment. The latter, joined with photography, enables us to produce copies of plans by papyrotypy.

I am aware that this paper must to many have been most uninteresting; but I was induced to bring the subject before the meeting to show that our authorities at the War Office are not averse to modern improvements in the small details of warfare. Our national sentiment can hardly be called "military," and the civilian element are always ready to believe that the British army can do little beyond being capable of mere physical fighting. A military man is not always fairly treated by his neighbours, and an absolute embargo has of late been laid upon the use of his brains by the right of patenting a useful discovery being withdrawn from him.

## THE PRACTICAL PRINTER IN AMERICA.

### VI.

#### MANIPULATIONS—PREPARING THE PAPER.

IN many respects the American practice of printing varies in greater or less degree from that of this country; but it is probably in the importance attached to fuming with ammonia that the greatest difference prevails. In America, fuming is universally practised, and Mr. Hearn gives minute details in regard to the mode of employing ammonia. It will be seen, also, that great stress is laid on drying the paper by heat, rather than spontaneously:—

*"Drying the Paper.*—The sheets of paper, while drying, should be placed about six or eight inches apart, so that they may not come in contact with each other, while damped, by means of slight draughts of air, thus spoiling the sheets of freshly sensitized paper—at least, those parts of the sheets where they meet.

"A gas stove is generally used for heating the drying room, partly on account of the little difficulty necessary to prepare it for heating, and then, again, on account of its small size. It does not occupy much room. An excellent one for the purpose can be obtained at a small expense.

"A soapstone, about six by eight inches in size, should be placed over the stove, and the gas turned on full head for a few minutes, until the stone has become very hot, then it may be turned down to a small jet. The reason why this stone is generally used is because it gives a diffused heat, and the sheets of paper may be placed quite near the stove, and also near each other, without waving enough to make them come in contact. The paper, in this way, is very quickly dried.

"During the summer it is not necessary to light the stove until all of the paper is silvered, and only then to dispel the slight moisture that may be on the surface.

"Usually during the summer season, while you are silvering the sixth or seventh sheet of paper, the first one or two will be dry enough to fume, so that an assistant

can go right to work at printing in about half an hour after you have entered the printing room in the morning.

"On damp days it will perhaps be necessary to keep the drying room quite warm for an hour or so in the morning, until you have silvered all of the paper necessary for the day's work.

"In the winter a stove is required a longer time than in summer, but there is no necessity for having the gas burning more than an hour or so during any day for the whole year round.

"It is on account of 'that terrible gas bill,' which is always coming around every month, that many photographers allow their paper to dry up spontaneously, and thus waste considerable time, when if a little attention was given to the time the gas should burn, the expense would be comparatively trifling. When the paper dries spontaneously, the surface of it dries dead.

"The paper should be dried quite quickly and thoroughly, for then the surface of it will be very brilliant and glossy, and the resulting prints will be much finer.

"Clean pieces of tissue or blotting-paper should be placed on the lower corner of the sheet, for the purpose of absorbing the silver solution which collects at that particular place, so that if the paper should happen to curl over, the corner would not come in contact with the rest of the paper in a wet state. To prevent the paper from curling up while drying, a stick having a spring nipper attached to each end of it is fastened to the lower part of the sheet.

"*Fuming the Paper.*—The paper, when thoroughly dry, is to be fumed. The advantages of fuming the sensitive paper are these:—

"1st. The paper prints richer, quicker, and more brilliantly.

"2nd. The prints tone easier, and in the finished pictures are much more pleasing and satisfactory.

"The printed fumed paper (when the nitrate bath is in good order, and worked properly) will print a very rich purple tone, tending slightly to blue in the hair, background, and light shadows, while in the deepest shades the colour will be very brilliant and beautiful. It is well known by experienced printers that the better the paper prints the better will be the finished pictures, and since fuming undoubtedly improves the printing paper, it has come to be a very necessary part of the printing process.

"The construction of the fuming box is very simple. Take any common wooden box large enough for the purpose, and make a door of suitable size for it, which, when shut, will totally exclude all light. Make a false bottom

in this about six inches or so from the real one, and perforate it with holes of about the size a large gimlet would make. These holes should be very numerous, and at the centre of the board there should be, if anything, a smaller number of them, because the saucer containing the liquor ammonia is generally placed at the centre of the real bottom of the box.

"Mr. W. L. Shoemaker's box may suit many better. He says of it in the *Philadelphia Photographer*:—

"I claim as an improvement an entirely novel method of causing a perfect and even distribution of the ammonia fumes upon all parts of a sheet, so that, if properly silvered, the sheet will give a perfect and even print.

"We have, in Mr. Moore's establishment, used for nine years a box which conveyed the fumes from the space in the bottom through holes into the fuming chamber, the sheets standing upright. But the objection is, that part of the sheet nearest the bottom is stronger than top or centre, which, when printing as we do, in whole sheets, invariably show a decided difference in the two ends. To avoid this, and cause a perfect distribution of the fumes, I have constructed an improved box. We have used this box constantly for nearly three months, and fumed hundreds of sheets in it, and can with confidence offer it as doing everything I claim.

"The amount of ammonia is no greater than formerly used; the time of fuming is increased two to three minutes. In all the old boxes in which no draft is used, the paper becomes damp or limpid, and quite decomposed on a warm sultry day. In this box the paper remains perfectly dry, no matter how long fumed.

"There is another advantage: when the box is opened, after fuming, it does not leave fumes in the room.

"A sheet of paper is tacked, or fastened by the American clothes-clips, to the bottom of each slide; another is laid on the top. When all are filled, pour ammonia into the dish below, close the door, open the draft-slide, and the fuming goes on. The box we are using is intended for full sheets, 18×22.

"The dimensions of the inside (fuming chamber) are as follows:—26 inches deep, 19 inches wide, and 17½ inches high. The slides are 19½ inches wide, 24½ inches long. The space below, for fumes, is 2½ inches high. The fumes are carried to the back end of the floor of the fuming chamber, which has an opening 1½ inches across its whole width, which allows the fumes to ascend into the first slide space. The first slide fits flush against the back of the box, and has a space of 1½ inches across its front end, which allows the fumes to ascend to the second slide space. The second slide has its opening at the back end, and allows the fumes to come into the third slide space, and so on, until we reach the top of the box. The chamber for carrying off the fumes has its opening at the front end of the box. The pipe for conveying off the fumes is placed at the back end of this chamber, on the top of the box. We use a two-inch tin pipe.

"It is necessary that the pipe should be attached to a chimney flue, or attached, as we have it, by what iron-workers call a "jacket," on the stove pipe. This is the best way, as you are always certain to have a good draft, which can be regulated at the sliding front of the door of the fuming space.

"It may perhaps be better, since it does not retard the time of fuming so much, to have a fine wire gauze placed about the same number of inches from the bottom of the box as was recommended above for the false bottom, and then the fumes of the ammonia will ascend more rapidly; and to prevent the ascension of it so very rapidly at the centre, and thus cause uneven fuming—especially at the lower part of the sheet—a piece of pasteboard can be placed on the gauze directly over and covering the greater part of the dish.

"This box should be made large enough for fuming three or four sheets of paper at a time, which is all that is necessary to fume at one time in most galleries, especially during the summer, when the paper discolours so quickly after it is sensitized.

"The sheets should be suspended in the air by means of a spring clip. Four laths, about three inches apart, and running parallel to each other, should be fastened to the top of the box, and a slip fastened to each end.

"By placing two sheets back to back, you can fume eight sheets of paper at a time should you wish. Place

about half an ounce of aqua ammonia in the saucer on the bottom of the box, shut the door, and then time the paper.

"Some persons use carbonate of ammonia for fuming, on account of its cheapness, but I do not see any gain in it, for what is gained by its cheapness is more than lost by its very insufficient fuming. Carbonate of ammonia is very often used together with the aqua by pouring a few drops of the liquid on the lump of carbonate. This is said to be an economical way of fuming the paper, for with the use of the carbonate it is only necessary for a few drops of the stronger ammonia to be used, for there will then enough vapour arise to accomplish our object effectually.

"Fuming with ammonia imparts a slight dampness to the paper, which, during the hot months of summer, may be considered an advantage; but during the damp days, when the paper is always damp, it is otherwise, and consequently the use of some substance in the fuming box is required, which will take to itself the moisture, and leave the fumes of the ammonia alone to act upon the paper. Chloride of lime is a good thing, and answers admirably. This is a moist, greyish-white substance, having, in a slight degree, the odour of chlorine. It has powerful bleaching properties, and prevents the paper from turning yellow while fuming, a very common occurrence during the hot months with some brands of papers. It also improves the printing qualities of the paper, gives a virgin whiteness to the vignettes, and prevents the discolouration of them after printing, when the discolouring occurs only from the heat of the printing room. It is best, when you wish to use this lime in connection with aqua ammonia, to pour a few drops of the liquid in the saucer, and uncorking the bottle of the chloride of lime to sprinkle a little of it on the ammonia, and immediately close the door. A dry white vapour of the lime and ammonia will ascend, which will give to the paper the properties named above.

"The paper while drying will curl up, thus causing it to fume unevenly. To prevent this, the lower part of the paper should be held by a lath, which has a spring clip nailed at each end of it.

"The time of fuming the paper depends upon the state of the nitrate bath, the quality of the negatives, the temperature of the weather, and the brightness of the light. Paper silvered on an acid bath needs much longer fuming than when silvered on an alkaline or a neutral one; paper for intense negatives less fuming than weak ones; during the summer less fuming than during the winter; and on a dark day less fuming is required than on a bright day. All these things are to be taken into account, and the beginner will do well to note them carefully.

"As to the first of these—the printing bath—if the bath is acid, the time of fuming should vary with the amount of acidity, and that time can be ascertained by fuming until it prints a rich colour without showing any signs of weakness. If the bath is alkaline or neutral, less fuming is required than if the bath is acid.

"As to the second of these—the quality of the negatives—a hard, intense negative should be printed upon paper fumed a very little, as too much fuming increases the sensitiveness of the paper, and makes the negatives yield harsher prints than what would be the result if the paper were fumed a less time. A thin or weak negative yields the best prints upon paper that has been fumed a long time, as it increases the sensitiveness of it, and makes greater contrasts, which is just what we wish. As for the medium negatives, fume a medium length of time.

"The temperature of the weather is also a very important item in considering the fuming of the paper. During the hot months of summer the paper can bear less fuming than during the winter months, when the strength of the bath and also the time of the fuming must be increased.

"The brightness of the sunlight must also be thought

of, for when the light is bright and the weather good, more fuming is required (so as to prevent meanness) than would be necessary if the opposite were the case."

## BENGAL PHOTOGRAPHIC SOCIETY.

### RULES FOR THE EIGHTEENTH ANNUAL EXHIBITION, 1875.

I. The exhibition will be opened in February, 1875, and will remain open for a month.

II. The exhibition will be open to all good photographs, contributed by members of the society, and by photographers resident out of India.

III. Only such photographs as have been taken within two years will be allowed to compete for the prizes now specified. No photographs may compete for prizes at more than one exhibition, and no prizes will be awarded to persons who have not actually taken the pictures which they exhibit.

IV. The prizes will be awarded on the recommendation of three gentlemen appointed by the committee of the society, and the judges may in any case consider whether or not pictures attain a proper standard of excellence; the decision of the judges will in all cases be final. The judges will be empowered to recommend the award of extra medals for photographs which they may consider of special merit, although not falling within the scope of the prizes offered as below.

V. Photographs intended for the exhibition must be properly mounted, but need not be framed, and must be delivered to the secretary by the 15th January at latest, accompanied by a memorandum describing the subject of the pictures.

VI. The carriage of photographs sent from distant places must be prepaid. The society will endeavour to have photographs (which do not obtain prizes) sold for the benefit of the sender, if request to that effect be made; but in such cases a price list must accompany the letter of advice.

VII. Exhibitors must make their own arrangements for the removal of their photographs the day after the closing of the exhibition.

VIII. Photographs to which prizes shall have been awarded at the exhibition, excepting local portraits, will become the property of the society, for distribution among members.

IX. The committee will select from the prize photographs two for distribution amongst members of the society, and the exhibitors will be required to give up the negative of these pictures to the society, or to enter into reasonable arrangements with the committee for the printing of the necessary number of copies.

X. An admission fee of one rupee shall be charged daily to visitors of the exhibition, members and subscribers excepted.

The following prizes will be awarded, viz:—

By His Excellency the Viceroy.

*Prize A—a Gold Medal.*—For the best single photograph in the room.

This picture is to be chosen first by the judges, and then to be excluded from competition for any other prize. *Open to all comers.*

By the Honourable the Lieutenant-Governor of Bengal.

*Prize B—a Gold Medal.*—For the best series of at least six \* Members wishing to compete for Prizes B and E are requested to state whether they are in the habit of disposing of their photographs for profit. photographic pictures, taken either in or out of India by any member of the society, not being a photographer by profession.

By the Society.

*Prize C—a Gold Medal.*—For the best series of at least six landscapes, taken and printed in India by any member of the society.

*Prize D—a Silver Medal.*—For the best series of at least six portraits taken and printed in India by any member of the society.

*Prize E—a Silver Medal.*—For the best series of at least six photographic pictures, landscapes or portraits, taken either in or out of India by any member of the society, not being a photographer by profession, to be selected by the judges from those for which no other prize shall have been awarded at this exhibition.

*Prize F—a Bronze Medal.*—For the best series of at least six photographic pictures, taken in India by any member of the society, to be selected by the judges from those for which no other prize shall have been awarded at the exhibition.

*Prize G—a Silver Medal.*—For the best series of at least six photographs of Indian subjects, exclusive of landscapes and antiquities, taken by any member of the society.

*Prize H—a Silver Medal.*—For the best series of at least six photographic pictures of Indian antiquities, taken by any member of the society.

## BY THE PRESIDENT.

*Prize I—a Gold Medal.*—For the best series of at least six photographic pictures of any kind taken in Europe, America, or Australia, excepting those, if any, for which the Lieutenant-Governor's prize has been awarded. *Open to all comers.*

*Prize J—a Silver Medal.*—For the best series of at least six photographs of young children. *Open to all comers.*

## BY CAPTAIN J. WATERHOUSE.

*Prize K—a Silver Medal.*—For the best series of at least six landscape views taken out of India, to be selected from those for which no other prize shall have been awarded at the exhibition. *Open to all comers.*

## BY T. H. BENNETZ, ESQ.

*Prize L—a Silver Medal.*—For the best series of at least six photographs printed in permanent pigments, by the carbon process or any of the photo-mechanical processes. *Open to all comers.*

## BY G. L. KEMP, ESQ.

*Prize M—a Silver Medal.*—For the best series of at least six photographs, reproductions of work of art, not smaller than 12 by 15. *Open to all comers.*

## NOTICE TO EUROPEAN CONTRIBUTORS.

Packages of photographs, intended for the exhibition of 1874-75, can be forwarded to India\* under the regulations of the Overland

\* The regulations of the Overland Parcel Post only apply to packages sent from the British Isles to India, and *vice versa*.

Parcel Post, full information of which may be obtained from the *Postal Guide*, or at the offices of the Peninsular and Oriental Steam Navigation Company, Leadenhall Street, London.

They may also be forwarded from London through the agency of the "Ocean Express," whose London Agents are Messrs. Nixon and King, 40, Regent Circus, Piccadilly, London, and 4, Agar Street, Strand. From Liverpool, through H. J. Simpson, Esq., of Messrs. Simpson, Lawrie, and Co., Liverpool.

Messrs. Kaltenbach and Schmitz, of No. 1, Alderman's Walk, London, also of Liverpool, Hamburg, and Bordeaux, have arranged to make up parcels of photographs for the exhibition, which will be closed and despatched from the above ports by the 1st November, 1874.

From Trieste, G. M. Rusea, Esq., will forward a parcel not later than the 10th November, 1874.

In order that the contributions may reach in good time, intending exhibitors are advised to forward their parcels from England not later than the 15th November, 1874.

Copies of the Rules will be procurable from the above agents, and any further particulars will appear in the photographic journals.

## LIGHTING THE SITTER.

BY FRANK JEWELL.\*

As there seems to be less skill displayed among the fraternity in lighting the sitter than in any other part of photography, and although much has been written on art principles as applied to photography, both as to posing as well as lighting, I shall endeavour to give a thoroughly practical and concise mode by which, with a little observation and some judgment, any one will be able to light a picture in an artistic manner.

It appears that many photographers lose sight of the fact that the parts of the face farthest from the eye should be darkest in tone, and the parts nearest should be lightest, with a gradation of tone from the light to the dark parts. I have seen many photographs by those high in the profession in which the reverse of the above is strikingly observable—that is, the back part of the cheek would be lighter than the front part. By a little thought you will see that this is an error. I want to impress the above on the mind of the reader seeking the key for excellence in lighting, as on this idea is founded what I am about to remark. We will suppose we are lighting a face in the old way—that is, with the most of the face in light. We will also suppose we are working with a top and side light, so arranged that any portion may be closed or opened at will. Should the sun enter in the least, some means must be adopted to stop it out entirely, and narrow frames, covered with tissue-paper, working on pivots close under the light, will do this effectually, while

they obstruct but little of the light. Any sunlight entering the room and striking the floor or walls will make bad reflections, and will spoil every effort to make the lighting as it should be. I have in my skylight-room a screen (similar to Kurtz's) about 4 by 3 feet, covered with white muslin, and fastened in a head-rest. This screen when placed over the sitter is about three feet from the head when at its highest point, but can be lowered at will. With the screen I control my light. My side-light is covered with material so thick that every trace of light can be effectually excluded, or let on at will. With this arrangement I get my high-lights. Bring your sitter out nearly but not quite to the centre of the room, and about four or five feet from the side-light, and turn the face so that the nose will point in a line parallel with the side-light. Move your instrument towards the side-light to get the view of the face wanted, and your background in the opposite direction to suit. You are now working diagonally across the room. Put your head screen in position over the head, taking care not to cut off too much of the light from the top. You will observe that there will now be a diffused light all over the face, only the side nearest the side-light will be a little the lightest. Now open a small portion of the side-light well in front of the sitter, which will let in a small amount of direct light, lighting up the prominent parts of the face. If the eyes are sunken, and there seems to be too much shade under the brows, lower the head-screen. This will light up the cavities, but will render the face flat in proportion. Now move your head-screen from over the head a little, and towards the shadow side of the face. This lets on more direct light from the top, and renders the face bold and vigorous again, with the eyes well lighted. The next thing to observe is, that the specks in the eyes (and they should always be there) are in both eyes alike. They should come on the top part of the iris, not over the centre, but more on the side nearest the side-light. Should the speck appear in one eye only, the face is turned too far from the side-light, and you get the effect I spoke of—that is, the back part of the cheek lighter than the front part, and to overcome this you must turn the face more to the sunlight, moving your camera to get the desired view, until this speck appears in both eyes. By turning the sitter more and more towards the side-light these specks are bound to come, and just as soon as they appear you may rest assured your sitter's face is lighted well and artistically. Of course you can make the contrast stronger or less by using your side-light. By this means you get that classic lighting of the nose, viz., a strong line of light down the bridge of the nose, and a high light on the tip, and you get the eyes perfectly lighted, and the rest will in every way be all right. This is my rule, and I have never known it to fail. To light a picture in the shadow style, do not move the position of the face, but move your instrument from the side-light to get a view of the other cheek. With, perhaps, a slight modification, the lighting will be just right.

PHOTOGRAPHIC MULTIPLICATION OF DRAWINGS, ETC.—Beneden states that paper, prepared as follows, costs but about one-sixth as much as the ordinary chloride of silver paper, and is as well adapted to the multiplication of drawings, and is simpler in its manipulation. A solution of bichromate of potash and albumen or gum, to which carbon, or some pigment of any desired shade, has been added, is brushed, as uniformly as possible, upon well-sized paper by lamplight, and the paper dried in the dark. The drawing, executed on fine transparent paper (or an engraving, or woodcut, &c.) is then placed beneath a flat glass upon the prepared paper, and exposed to the light for a length of time, dependent upon the intensity of the light. The drawing is removed from the paper by lamplight, and, after washing the latter with water, a negative of the drawing remains, since the portions of the coating acted on by the light become insoluble in water. From such a negative any number of positives can be taken in the same way.—*English Mechanic*

## A LANDSCAPE STUDIO.

A WELL-KNOWN modern painter in water colours—whose work was, however, largely confined to the drawing-book school of art, in which the well-known rustic cottage, delapidated cow-house, or old water-mill was an inevitable principal foreground object, whilst brown trees and blue distance were *de rigueur*—once remarked that “going to nature put him out.” Nevertheless, the best painters rarely paint any subject, figure or landscape, realistic or imaginative, without a careful study of nature: the living model for figures, and the whole face of nature for landscape. The same statement is true of all conscientious and capable photographers. They go to nature for their best effects. Some readers will smile for a moment, and mentally reply, “The photographer can do nothing else, as the camera cannot imagine a picture, and produce it as a painter can.” That is perfectly true; but the photographer can do something much worse. He can get a scene-painter to produce him backgrounds in which impossible arcades, trees and shrubs unknown to botanists, and marvellous mountains, vie with each other in confusing the effect of reality in the picture. But the conscientious and capable photographer goes to nature. The finest results in pictorial photography have been so produced. Mr. Rejlander has always worked in that direction. Mr. Robinson's work furnishes notable illustration: he has often travelled miles for a tree here, a stream there, or an effective distance still further on, each simply as elements in one picture. He has planted banks of wild flowers, grown trees, made lakes, where he could not find the required combination in nature. For it must be borne in mind that whilst nature in her truth must form the elements of a true picture, it is the province of art to select and combine nature so as to secure the highest pictorial effect. But whilst the most capable successful artists in photography have taken much trouble to build, or grow, or combine natural effects for especial pictures, hitherto but little has been done in the systematic formation of what we must term, for want of a more distinctive name, landscape studios, in which a multiplicity, and, in fact, almost infinite variety, of natural effects may be produced in conjunction with portrait figures, the lighting and general arrangement still being largely under the control of the artist.

Such a landscape studio has just been formed by Mr. Samuel Fry, at Kingston-on-Thames. Having the good fortune to find in the rear of his existing business pre-

mises a piece of vacant ground, he resolved to acquire it for open-air work. Nine months have transformed this piece of waste ground, which had become a receptacle for delapidated pots, pans, and waste material of all kinds, which by some process of natural selection seem to find a home on any spot which is abandoned to neglect for a few months, from a rubbish heap into a singularly complete epitome of landscape effects and studio arrangements which can be desired. As a pleasant garden, bright with flowers, trees, shrubs, and water, admirable in arrangement, the place is charming, whilst for special photographic purposes it is most satisfactory.

It would be difficult to give a very complete idea of the arrangement by any verbal description; but we may suggest something of its character. The piece of land is not large—probably not exceeding half an acre—but, by skilful treatment, it is arranged to admit of pictorial effects suggestive of indefinite extent. At first glance it presents a happy mixture of shrubbery, parterre, and country lane. It is entered by a gateway leading to a carriage sweep sufficiently long and wide for a carriage and four to be driven into position for photographing, a large wall, forming the end of a building, being roughly plastered for use, if desired, as a plain background, the position being happily chosen to secure a north principal light, the south being shaded by rapidly growing poplar trees. Passing on beyond the carriage drive, we reach a rustic gateway, formed by stumps of trees, already forming a fine pollard head from having rooted where they were placed, whilst an abundance of creepers, wild and cultivated—pre-eminently a charming mixture of *trapaolum Canariense* and *clematis Jackmani* in very full flower—clinging around. Leaving the drive by this rustic passage, we are startled next by the sight of a lake; not very large, it is true, but big enough to float a capital practicable boat of about ten feet long. The lake is probably not thirty feet long by seven or eight feet wide; but, being made to form a bend in the grounds, its precise size will never be discovered in a picture. The path round this lake, and leading to the rustic boat-house, is a charming bit of wild growth. The path is thickly tangled with common British plants: here are brambles and briars; varieties of the dead nettle and common nettle; wild carrot, charlock, wild ranunculus, euphorbia, dog mercury, stitchwort; varieties of sonchus and carduus; several kinds of ivy; various grasses and rushes; and many more than we could note or remember. Various water weeds have already taken possession of the lake, which has facilities for changing, when necessary, the supply of water, and so preventing stagnancy. Leaving the lake, we perpetually meet with new effects, all especially designed for pictorial value. There are three or four different rustic sheds or summer-houses, surrounded with varieties of ivy and other climbing plants, and thatched with heath; large banks of choice bedding plants, and others with wild flowers. A large variety of conifers and other evergreens are used in completing the arrangement, and shade and pictorial effect are sought by means of rapidly growing deciduous trees, such as limes, poplars, sycamores, &c. The primary thing necessary to success which we find illustrated here is the evidence of a carefully wrought out design, in which a great variety of distinct and excellent effects are comprehended; and, second only to this, the rapidity and perfection with which the results have been obtained. Everything needed to be begun *ab initio* nine months ago. Upwards of a hundred loads of garden mould or loam, and upwards of fifty loads of gravel, had to be brought in; hundreds (probably thousands) of plants, shrubs, and trees had to be planted; and in nine months the place bears the blooming and full appearance of the growth of years. We can scarcely with propriety be so unfair to Mr. Fry as to recommend photographic visitors who may unnecessarily occupy his time; but to all who can, we should not the less recommend getting a sight of this landscape studio.

## A PHOTOGRAPH OF DOTHEBOYS HALL.

BY H. BADEN PRITCHARD.

A TOURIST photographer has quite sufficient difficulties to contend with in the ordinary way, with sensitive plates, camera, stand, selection of points of view, focussing, &c., and it is rather trying, therefore, when other vexatious obstacles have also to be surmounted. I was in Yorkshire the other day, footing it over the moors, through the beautiful Wensleydale, ascending Hillborough, and visiting such out-of-the-way spots as High Cup Nick, Cauldron Snout, and Conky Sear. Any one who believes it is necessary to go abroad—to Norway, or some such remote region—to get away from towns and every-day life, should cross from the "High Force Inn" in Teesdale to Ilwaco and Ulleswater, and he will find a two days' march before him through a district as primitive and secluded as the greatest hermit would desire. During twenty miles of the way he will scarcely see a habitation or meet a living soul on the wastes of moorland, in the savage defiles, or about the foaming torrents, by which his way passes. We say way advisedly, for there are no paths in some parts, or, if there be, these are worse than useless, enticing the traveller from the right direction. There is only one guide to be relied upon in walks such as these, and that is the compass, aided by the Ordnance map; and one must place implicit reliance upon its direction, deviating neither to the right nor the left, however tempting the little paths on each side may appear. Nothing is so treacherous as these temptations. Over stony ground they appear plain enough, but once a swamp is reached, or thick heather, and they vanish altogether, or break up into half-a-dozen sheep tracks. "Follow your compass blindly," is the only advice to be adopted when the traveller is at fault; and when he is certain of having crossed the highest point, and only desires to descend then let him follow the course of a streamlet or torrent carefully, which will lead him into the valley to a point where he will be enabled, by map or other information, to adopt a better path.

But I am straying from my subject. From Teesdale I came down to Greta Bridge, Yorkshire, possessed with an ardent desire to obtain a photograph of Dotheboys Hall. To the village of Bowes is a five-mile walk—Squeers and Nicholas, it will be remembered, drove over in a pony chaise—and then the problem was to find out the spot. The good people of Yorkshire are a frank, open-hearted race, but I had my misgivings about the inhabitants of Bowes possessing any love for Dickens after his exposure of cheap boarding schools, and I was very right in my assumption. However, by far the greater portion of the villagers have never so much as heard of Dickens, and a deep-set scheme on my part to have a pipe and glass one evening at one of the ale houses, and so get into conversation with the cronies of the place, was altogether unfruitful. The old landlady of the inn was, however, better informed, and after expatiating on the interesting character of the town, the old Roman encampment, the Norman castle, the grave of the lovers "Edwin and Emma," whose story has been sung by poets, I cautiously approached "Dotheboys." I at once touched an unpleasant subject, and my kindly hostess waxed wrath, and it was only by introducing the Romans again, and interesting myself in a big five-foot wall in the kitchen, which was supposed to date from that period, and which I tapped and examined with the assiduity of an antiquarian, that I found myself in smooth water again. I had found out two things, however: the locality of the building, and the fact that the village people looked with no favourable eye upon disciples of the great novelist. A search the same night in the dark brought me to my destination, and the next morning I made a further reconnaissance. A long, low, stone building, just outside the village, was the spot, and from the Norman castle, where I took my camera, a good, if distant, view of the front was obtainable without observation. To take the rear of

the building it was necessary to be cautious. I fixed on the place for setting down my camera—on a low stone wall—and looked with one eye to estimate roughly how much of the building I could get into the picture. I counted the paces to judge distance, and then focussed an object at a similar interval. My plate was put into the camera, the slide drawn, and, accompanied by a friend, we moved towards the building, set down the camera, uncapped the lens, and then turned away and became exceedingly interested in a dog cart standing in the road.

Securing the picture made me bolder. I passed the side door and looked in. It led into a yard showing the back offices, the well or pump that used to become frozen in winter time, and make it necessary occasionally to substitute a "dry polish" for washing on the part of the boys. There, too, was the stable where Smike would rub down the shaggy pony. If I could only get a picture of this I should be happy. Some children came out on seeing us, and called out, "There's noobody in; there's noobody in." This decided me. I calculated roughly the distance as before, slipped in a plate, and while my comrade conversed with the children in a moral tone, I placed my camera on a convenient step. Exposure began, and I had just given twenty seconds, when my companion, who had never ceased speaking to the children, whispered in French, "Gards toi."

I capped at once, and saw behind me a woman approaching with a big stick. I swept camera, plate, and slide under my arm, and made a clean bolt of it; but the object of the good Yorkshirewoman's indignation was not myself, but an unruly cow that had escaped into the road.

## PHOTOGRAPHIC JOURNALS AS CENTRES OF PROGRESSION.

BY W. T. BOVEY.

ALTHOUGH, as a rule, I expend but a slight amount of thought on the reception my communications meet with, yet, for the nonce, I frankly confess to an experience of pleasurable anticipation on account of the promising prospect opened up by my recent chance shot—a prospect which bids fair to restore to photography those feelings of zeal and of interest that gave an impetus to the industry of its old workers, whose combined efforts ultimately made our art what it now is—a legitimate offspring of science, twin-sister of art, a marvel of ingenuity and of rapid progression. As a matter of course, there are not found wanting those good-natured friends whose keenness of vision never fails when motives pass under review; and, equally as a matter of common occurrence, judgment is based on desire rather than on evidences of fact. The friends here alluded to have not scrupled to assert that my "pretended" impromptu suggestion was part of a well-matured scheme concerted between myself and the Editor to bring up what they are pleased to fancy are "the waning fortunes of the NEWS."<sup>\*</sup> Unfortunately, however, for the truth of the story, I had not seen the Editor for nearly three years, and no private communication by letter had passed on the subject at all. Hence the charge of collusion becomes an absurdity, and new motives are on offer for judgment, which, summarily disposed of, might be given in very few words—offshoots of over little natures indeed.

The existence of a friendly rivalry among photographic experimentalists, and the upholding of the dignity of our art-science, have from the beginning been objects of interest to me; and I may look back on the past with feelings of satisfaction, inasmuch as I have never missed an opportunity of advocating the cause of advancement, or of defending the art when its claims on respectability have been thoughtlessly assailed; and, consistently with a

\* It may interest those of our friends whose attention may be arrested by the phrase here quoted to know that the "fortunes of the NEWS," so far from waning, have never been in a more satisfactory condition.—Ed.

practice I have faithfully followed for over twelve years, I shall not now hesitate to point the way to peace and progression, even though my plans include in their design the elevation of tone and a general improvement of our journals, which, I am free to acknowledge, is the object I have now before me, and on which I purpose treating in my present written discourse.

Photography has no room for jealousies, it being cosmopolitan in its associations, and having no class interests to consider in its rapid transitions. Princes have not disdained to become initiated into the mysteries of the dark room; and, from the seat of royalty down to the humble labourer's home, rank in all its varying degrees has derived profit or pleasure from a practical companionship with the implements of our art.

An art-science like photography, that can fascinate whilst it enlists the services of the million, must perforce attract around it a republic of workers whose common interest it is to compare notes of experience, and to do what they can to promote the maintenance of good feeling. For photography, unlike most, if not quite all, other arts, is surrounded by so many invisible influences to make or mar its productions, that it becomes an absolute necessity for secret dodges to be ignored; that every discovery made should in some form become public property; and if this necessity is repudiated, the art must virtually suffer, simply because a link is found wanting in the chain that connects present knowledge with means of future improvement. This latter remark at once leads us to consider the services rendered by our journals.

I have already remarked that photography belongs to no class—that its workers count many thousands. I now direct attention to the important fact of an almost complete disintegration existing in the working elements just now briefly referred to; which last might be likened to rivulets that are made useless by isolation, and remain so until the channels are extended, and new directions given towards one focus, which forms the reservoir. From thence a fresh start is given, and that which before was scarcely of value is turned into a direction of general utility. To make the simile complete, I have only to direct attention to the numberless isolated experiences which from time to time have been collected together in the pages of our journals, and from thence distributed throughout the civilized world, to the advantage of every practitioner of the art, and with priceless benefit to the onward movement of photography. And thus in a few words is shown that if photography is to continue to progress, the photographic journals must perforce be regarded as indispensable centres of progression.

The purity of the water that is distributed from a reservoir must depend on the amount of care taken in conducting the process of filtration. In like manner the utility of matter emanating from photographic journalism in a great measure depends on editorial sifting and scrutiny. Unfortunately, even those who act as pilots of journals are mortal, and too frequently err in their calling. And to this, in some measure, is due the disasters which have temporarily clogged the growth of photography. For example, secret mongering is a legitimate subject for advertisement, but it is misplaced kindness to permit anyone to puff up his wares in unpaid-for letters to the editor, because the insertion of such communications lends importance to the writers. And many a "gull" has been plucked indirectly through such agency.

Again in the cases of differences of opinion that occasionally arise. Those who suffer real or imaginary grievances have certainly a right to make their wrongs known; but just as a man who acts as his own lawyer has a fool for a client, so are those who write under circumstances provocative of anger the most unfitted for calmness of expression. And it is within the proper duties of an editor to modify expression, and so soften down what otherwise must act as a torch to kindle fresh fires. In point of fact, a

melancholy example of this kind occurred but a few weeks ago. A nice little quarrel had been raging, the merits of which I care not to discuss. At all events, it must have been noticed that words grew wilder and wilder, until they culminated into the vilest of abuse, that not merely went the whole length of coarseness and wretched vulgarity, but, fearing that the persons lampooned, and drawn, evidently, from familiar pot-house models, should, in such characters, scarcely be known, the foolish writer did not scruple to introduce ills of bodily affliction, wrought by an inscrutable providence, into his word-picture, which, for the honour of our art, I sincerely hope has found no admirers to applaud. The editor was clearly wrong in permitting so monstrous a folly to appear in his pages, and if he imagines that the applause of a few represents the opinions of the many, the sooner he is convinced of his error the better it will be for his paper. And the more advantageous will it be for himself.

The NEWS of last week was, to myself at least, a reminder of what our journals used to be; and the ready responses to the invitation issued but a week before by its editor are so many proofs that the old spirit of generosity was only suspended—that photographers are now, as they ever were, ready to turn on supplies of information if they can be persuaded that photographic journals may, without fear of abuse, be used as centres of photographic progression.

Having unburdened my mind of thoughts which have for their object the addition of interest in the art, and of success to our journals, I trust for a while to find no more occasion for lecturing, as I hope to be able to expend some little time on those subjects made matters of queries.

#### NOTES ON COLLOTYPE PRINTING.

BY CAPTAIN WATERHOUSE, R.E.

IN the number of the PHOTOGRAPHIC NEWS for the 9th January I see that a correspondent, signing himself "Bichromate," has been enquiring why the colotype plates prepared according to my formula, with tannin, cannot be sensitized by the addition of bichromate to the mixture of gelatine, tannin, and soap. In my early experiments with the process I found that the bichromate could not be added to the mixture without causing a precipitate, and therefore the plan of sensitizing in a separate bath was adopted; and though it necessitates a double drying, it has been found to possess the advantages of enabling the gelatine film to be prepared at any time quite independently of the sensitizing, and to be dried in the open air, a mode which seems, in suitable weather, to give better results than drying by artificial heat in a stove.

My attention has been drawn quite lately to the subject by seeing that, in the second edition of his excellent "Instructions in Photography," Captain Abney, when describing my method of sensitizing, says, "If the same proportion of bichromate salt be added to No. 1 (the solution of gelatine) as given in the heliotype process, this re-drying may be avoided." I therefore repeated the experiment, but found that a thick clotted precipitate was formed immediately on the addition of the tannin and soap to the mixture of gelatine and bichromate. In a recent experiment, in which the bichromate was added to the mixture of gelatine, tannin, and soap, a very few drops of a saturated solution of bichromate of potash sufficed to turn the mixture into a stiff jelly, and to render the gelatine insoluble and useless. It would appear, therefore, that the plates must be sensitized in a separate bath.

It will, I think, be found impossible to combine the tannin with the bichromate in an *alkaline* mixture without producing chromium compounds, which would have the property of rendering gelatine insoluble. In an *acid* solution it might be different. I have not tried this, but will take an early opportunity of doing so, and will let you know the result if it should appear worth recording.

NOTE ON SALTS OF IRON SENSITIVE TO THE ACTION OF LIGHT.

BY WILLIAM H. WATSON.

As has been frequently remarked, a fact in science once clearly ascertained, is almost always productive of good, at once or hereafter; so I trust the sensitive salts of iron may prove to be in the wide field of photography.

In my communication which appeared in the pages of the PHOTOGRAPHIC NEWS for the 14th inst., I alluded briefly to some experiments which showed that ferrous tartrate is acted upon by the photo-actinic rays. I have continued, since then, my experiments on this point, and have found that ferrous citrate is also sensitive to light, and about as much so as the tartrate. In testing these salts in this respect, I floated for some ten to twelve minutes on a solution of the salt, dried, and exposed under the negative. The result was a faint image upon those parts of the paper on which the light had shone—a reddish brown deposit—ferric oxide.

This is sufficient proof of the sensitiveness of the salt; but to make the image more dense was then the object. This I readily managed by the use of gallic acid. The paper, after exposure, was first well washed in warm water, then in weak acid, again washed in water, and afterwards dipped into a solution of gallic acid. The iron remaining in the paper after washing combined with the gallic acid, resulting in the formation of the gallate of iron (black). This is the black colouring matter contained in ink, so that if at any time, with further improvements, this process were adopted for printing, the prints would be equally as stable as pen and ink etchings.

From this it would seem that the action of light is one of oxidation; and yet, from other experiments, it appears to be deoxidizing—as, for example, the change in nitric acid, from that to nitrous:—

Ferrous citrate or tartrate may be prepared as follows:—

1. By adding to a solution of ferrous sulphate, one of potassic, sodic, or ammoniac tartrate or citrate.
2. By dissolving metallic iron in tartaric or citric acid.
3. By precipitating from ferrous sulphate, by ammoniac carbonate, ferrous carbonate, and by dissolving this in the acid.

The reaction is as follows:—

Ferrous salts are of course changed from the ferrous to the ferric state on exposure to the air. To avoid, then, precipitation of ferric oxide, a little acid should be added in excess. The paper, after preparation, should be kept under pressure.

It seems only reasonable to suppose that the salts formed by the combination of the other organic acids with ferrous oxide would be sensitive also, this from their similar compositions, as under, but not proved, so far, by experiment—

Tartaric acid	...	...	...	...	$C_4 H_6 O_6$
Citric acid...	...	...	...	...	$C_6 H_8 O_7$
Malic acid	...	...	...	...	$C_4 H_6 O_5$
Lactic acid	...	...	...	...	$C_3 H_6 O_3$
Succinic acid	...	...	...	...	$C_4 H_6 O_4$

I have made experiments with ferrous acetate also, but failed to get the same result as in the former cases.

Apart from what may be the practical photographic nature of the matter, it is one at least worth knowing, from a purely chemical point of view.

I enclose, Mr. Editor, two prints.

No. 1. Paper floated on twenty to thirty-grain solution of ferrous citrate, dried, and simply exposed under negative after keeping for three days.

No. 2. Paper prepared as No. 1. After exposure was washed in water, washed in weak acid, again washed in water, dipped in solution of gallic acid, washed, and dried.

I may add that they were exposed about three-quarters of an hour in direct sunlight.

ON PHOTOGRAPHY IN RELATION TO THE TRANSIT OF VENUS.

BY CAPTAIN ABNEY, R.E., F.R.A.S., F.C.S.\*

As is doubtless well known to all, there will be an application of photography to register the passage of Venus across the sun's disc, and it may not be amiss to give an outline of the processes that will be adopted.

It has been determined by the Astronomer-Royal that at each photographic station a photograph shall be taken every ten minutes during the transit, and it has been a matter of considerable labour to work out a process that will admit of such a large number of negatives being taken in a hot climate. In Kerguelin's Land it would be perfectly feasible to adopt the ordinary wet process, the low temperature admitting of it; but in a temperature of 90° Fah. the evaporation of the volatile constituents of the collodion would render such a process inapplicable, as all practical photographers will admit. In India, where I have worked extensively, coating two or three plates in summer in a large-sized tent has sometimes proved injurious. With such experience I venture to think that it would have been madness to have trusted to the wet method for four hours, unless the conditions of personnel of the parties was considerably altered. Sir G. Airey, after much anxious deliberation, and with the advice (and that not hastily formed, by any means) of Mr. Warren de la Rue, determined to adopt a dry process, if practicable. After considerable experiment, conducted at Chatham, it was determined to adopt a collodio-albumen dry process, using a highly-bromised collodion and strong alkaline development.

There were several advantages in this: first, at the critical time the photographers would have nothing to distract their attention excepting placing the dry plates in the slide, and developing every twelfth plate exposed in order to regulate the exposure; second, the irradiation was much diminished by the use of albumen—a point of no small importance when measurements have to be taken; third, the shrinkage of the film is reduced to zero when the plates are properly prepared.

In regard to the first advantage claimed, it will be apparent that plates prepared at leisure will be superior to those prepared in the hurry of the moment, as would be the case with wet plates. The chances of stains and spots are diminished tenfold, and one may expect a much cleaner picture.

The true explanation of irradiation has been argued of late in Nature, and, perhaps, I may be pardoned for dwelling an instant on that point. Irradiation may be divided into two kinds, viz., that occurring from reflection from the back of the plate, and that occurring from reflection from the particles of bromide or iodide of silver in the collodion film. The first requires no explanation. If a film be sufficiently dense, and of such a colour as will cut off the most actinic rays of the spectrum, no irradiation on that account need be anticipated. Iodide of silver fulfils this condition much more fully than does bromide of silver, the former approaching to a yellow colour, whilst the latter is almost white. A thin layer of iodide is much more efficient in cutting off the blue end of the spectrum than is the bromide; hence, if irradiation through reflection from the back of the plate is to be overcome, it is wise to use a certain proportion of iodide in the collodion. Practically, I have found that in the dry process under consideration, three parts of iodide and two of bromide give the best results, without diminishing the sensitiveness of the film.

The second cause of irradiation, viz., reflection from the particles of bromide and iodide, is not hard to explain. When a colloidal body, such as gelatine or albumen, is brought in contact with a soluble salt of silver, the resulting compound is found to be one which is singularly free from this defect. If a ray of light be allowed to fall at a right angle upon a very thin cell containing an emulsion of bromide of silver, the cell having worked-glass

\* Read at the meeting of the British Association at Belfast.

sides and ends, it will be found that the ray of light will be scattered considerably, apparently in a logarithmic curve; the surface nearest the source of light will not be affected, but it will spread from that surface towards the other, a physical line of light becoming an area. If, however, a colloidal salt of silver be introduced it will be found that this area is much diminished, and, for small distances, becomes inapplicable. In connection with this I may mention that bromide plates, even when backed with a non-actinic backing in optical contact with the plate, will give irradiation with alkaline development, while with acid development the irradiation will disappear. The explanation is not far to seek. The alkaline developer reduces the silver *in situ*; the acid developer deposits silver on the surface, and where there is most attractive force. In the former case the dispersed light acting on the interior of the silver causes the necessary change in the bromide of silver, and affects the reduction. Daguerreotype plates are not free from irradiation, as has been supposed, although, owing to the extraordinary thinness of the iodide of silver, but little effect can be traced unless a very prolonged exposure be given.

In the dry process selected for the transit of Venus it has, then, been thought desirable to have a rather dense film, containing a proportion of iodide of silver, and a colloidal body—albumen—as preservative. I am not unmindful of the fact that different pyroxylines more or less affect irradiation, and I have altered the constitution of the pyroxyline in the collodion we shall use by adding certain proportions of water. This materially aids the annihilation of irradiation from these plates.

For registering the time of external and internal contact of the planet with the sun's disc, the method known as "Janssen's" has been adopted, viz., causing a fresh portion of a plate to be exposed every second during the critical time to the sun's limb at that part where the contact will take place. Mr. Christie and Mr. De La Rue have both devised a slide for this purpose. The English parties use that designed by the former, whilst Colonel Tennant will use that by the latter.

Shrinkage in the film has been carefully looked for by Dr. Vogel, of Berlin, and also in this country by Colonel Stuart Wortley and myself. Photographing a grating of two hundred lines to the inch, by contact printing, and measuring the results, I have been unable to find any alteration in the distances of the lines at any part of the film; hence I feel confident that any shrinkage that can take place will be so small as to be negligible. The Russian parties are, I believe, going to use a grating material of cross wires. If shrinkage did occur, this would be necessary, but it seems almost useless—in fact, hurtful—when there will be none. There must be a certain error introduced due to the grating itself. The method of finding the angle of position of the wires will be determined photographically. Two pictures of the sun will be taken at an interval of one minute on the same plate. The line joining the intersection of the sun's images will give the angle of position of the wires when measured by the micrometer.

At each station the photographic party will consist of one officer and three Sappers, all of whom have been trained in the use of the photo-heliograph and the process employed. A drill for each operation has been devised, and it is anticipated that the dangers of excitement during the critical time have been overcome by this arrangement. Practice on a mock transit has ensured a thorough knowledge of each phase of the phenomenon, and I apprehend that discipline, combined with a trust in their superiors, will have annihilated one source of failure.

#### THE PHOTOGRAPHING OF THE MOON.

In the Mathematical and Physical Section of the British Association the Earl of Rosse, F.R.S., exhibited a large photograph of the moon, which, he said, had been lent to

him by his friend, Mr. Warren De La Rue, who had much to do with the construction of the great reflector of the Melbourne telescope, with which the picture was taken. Although the great telescope at Melbourne had been in use for some time, it was the first really successful photograph of the moon which had been taken with it, partly because the reflector had been used for other work, and partly because the nights on which good lunar photography is possible are so very few. Currents of air of different densities were usually moving in large volumes one above the other, and these so refracted the rays of light as to cause the stars to appear to the eye to twinkle, and to cast unsteady images of the different parts of the moon when the reflector was used in the attempt to obtain photographs. Hence not only must the sky be clear, but the air very still at all elevations before good lunar pictures can be obtained; so it was not surprising that in the short period which elapsed after the reflector was made, and before it left Dublin, no good photographs were taken. Before the advent of the photograph he was then exhibiting, the best that had ever been taken had been obtained by Mr. Rutherford, of New York, who used a refractor for the purpose; the lens had been made specially for the work, and had been ground to bring the blue and violet rays of the spectrum to a sharp focus on the sensitive plate, since these rays, and not those which are most luminous to the eye, are those which exert an influence over the chemical substances contained in photographic films. Mr. De La Rue had taken many beautiful photographs of the moon, at his observatory at Cranford, and was noted for his skill in the work; but he believed that Mr. De La Rue was of opinion that Mr. Rutherford had obtained a better photograph of the moon than himself, the atmospheric conditions chancing to be so good on one particular night. Although Mr. Rutherford had obtained his good picture so far back as 1865, he had never been able to obtain another to equal it since; therefore the single picture did not prove that a refractor was better than a reflector for lunar photographic work, but simply that atmospheric conditions were exceptionally good on a particular evening. He had carefully compared Mr. Rutherford's picture—of which he possessed a copy—with the one taken with the Melbourne reflector, and thought that the latter was slightly the better of the two. He could not, however, speak with certainty, and should like to have the aid of good photographic critics. Both pictures had been enlarged from the original negatives, and Mr. Rutherford's had been much more enlarged than the other. The original negative taken with the Melbourne reflector was about three and a half inches in diameter. The phase of the moon was nearly the same in both pictures.

Mr. James Glaisher, F.R.S. (of the Royal Observatory at Greenwich), said that Mr. Rutherford had recently taken a photograph of the moon nearly as good as the celebrated one which he took nine years ago. He knew this, because Mr. Rutherford had recently sent him a copy of the last one.

Professor Jellett said that after the great reflector first reached Melbourne some unfavourable remarks were made about it, but the results before them showed that it was a good instrument. He was glad to say that that admirable telescope had been made in Ireland.

#### Notes and Queries.

##### PHOTOGRAPHING FLOWERS.

SIR,—I have often seen wild flowers growing near an old mill in Cheshire, beautifully white, without losing in detail, where the fine mill dust had precipitated itself on them. Could not this be applied to photographing flowers?

I should, however, prefer violet powder dusted in a fine cloud from a puff or muslin bag, to shaking a flour-bag over them. I think this would have met the difficulty of "O. G. R." with the sunflower, also that of the lady.

H. GREGGON.

Correspondence.

THE STATUS OF PHOTOGRAPHY.

SIR,—I am glad to see this discussion revived, and beg to say a few words on the subject.

The principal cause of the low estimate the public have of photography is due to the low prices for which photographers are content to work; and so long as this is the case, so long will the public despise us as a body. To attain respectability, we must estimate ourselves justly, and put a proper value upon our time.

How often does it happen that, from causes entirely beyond our control, an unsatisfactory or bad photographic portrait is produced! Our clients, as a matter of right, demand a re-sitting, which, if not accorded readily, leads to unfriendly discussion, loss of business, &c. Re-sitting is a subject of the greatest importance, and ought to be regulated by a committee of professional photographers. In my practice as a photographer, I am continually told by clients that Messrs. So-and-So, without hesitation, grant them any number of re-sittings. I have been told by ladies that they have had as many as twenty re-sittings without extra charge. It is difficult to meet such wild and untrue assertions with any degree of patience; but the fact that such assertions are made proves of how little value our time is considered.

Another cause of the low estimate in which we are held is our craving to be considered artists. Artists cannot and will not allow photography to be a fine art. That the public do not consider photography a fine art is evinced by the exclamations they make use of in looking at photographs:—"Here is a lovely photograph, just like marble!" or "Here is a fine photograph, as sharp as a needle!" or, again, "What a beautiful photograph: how clear, how bright, how smooth, how soft!"—never "How like nature!"

Some time ago the subject of the claim of photography to be considered a fine art was discussed in your paper at great length, with no definite result. A letter from Mr. Cocking appeared to me to settle the whole question. In a dream, he saw a photographer and an artist, with their materials, entering into Madame Tussaud's exhibition, and each in his way, and with his different materials, produced a picture of one of the historical groups there exhibited. On comparing the two pictures, the photographer's was found to be only a mechanical representation of a series of dummies; whilst the artist had infused into his group, individuality, expression, ideality, imagination, and other intellectual qualities; he had, in fact, painted his own mind, his picture in consequence was interesting and valuable, inasmuch as it expressed qualities apart and distinct from the groups from which he had made his picture.

Every photographer who will consider this subject cannot but perceive that his art is limited to imitation, and that he can only reproduce what already exists in his model. Imitation is only one quality, and the lowest, of a picture having any pretension to be considered a work of fine art. Before the status of photography can be determined, this question ought to be finally decided, and photographers ought to be content to be photographers, and leave art claims alone.

No doubt a photographic society, the membership of which could only be attained by thoroughly competent photographers, would tend to raise their position; but such a society ought to have for its president a professional photographer, and not, as Mr. Aldridge suggests, a man in a different profession. Scientific men, eminent men, and amateur photographers, might be invited to become honorary members. We have only to follow the example of the Royal Academy and other fine art societies, who have always had professional artists to preside over and conduct their affairs. Photography has a position and aims of its own, distinct and apart from fine art, and a man of ordi-

nary abilities might well be content if he succeeded in mastering all its difficulties. A photographic society whose members were only photographers of acknowledged ability would soon establish a position, and would be able to give laws to govern and guide the respectable members of their profession—in fact, just as the Royal Academy did. Membership of such a society would be regarded as an honour by photographers, and would be a certificate of merit in the eyes of the public.—Your obedient servant,  
PHOTOGRAPHER.

PICTORIAL BACKGROUNDS ADDED TO NEGATIVES.

MY DEAR SIR,—In reply to your correspondent "W." I beg to enclose you a specimen of the background printing referred to. I also enclose a print from the twin negative without the pictorial background, so that you may see that the conditions are changed exactly in the proportions I said they would be—i. e., the negative slightly intensified. I have printed several copies, and see no difference in the latter impressions.

The bichromate can, however, be washed out without any injury to the adjunct background; but I maintain that after-washing is quite unnecessary. If any of your readers will kindly call, I shall be most happy to show them the unwashed negative, and the result, in the form of a print similar to what I send herewith.—I remain, dear sir, yours truly,  
J. WERGE.

P.S. The prints I send are not high class specimens either of photography or the application of the process. I simply took the first portrait and pictorial negatives I laid hold of, and combined them to confirm my first idea.

[The prints forwarded bear out Mr. Werge's statement. The print from the negative with the bichromate shows that an effect of intensification is produced; but the intensification has produced a harsher, coarser result. We append Mr. Werge's instructions, which he encloses.—ED.]

Take the sitter against a dark background, and finish the negative in the usual way, but do not varnish it. Allow the negative to dry, wet it again, and pour over it the sensitive mixture of dextrine, &c.; drain, and dry over the spirit lamp (or, better still, lay the negative on a hot-water drying-bath in the dark room, or by lamp or fire light). When dry, and while still warm, place the pictorial negative from nature, or from an engraving or painting, in contact with the other negative, face to face, and expose, pictorial negative uppermost, for about twenty minutes in a strong light. Then take the negative into a dull white light, or strong yellow light, and remove the pictorial negative without scratching. Lay the portrait negative on a retouching desk, and apply the plumbago all round the figure with a camel's hair brush until the pictorial background appears, and is dense enough. If there should be any difficulty in obtaining sufficient density, breathe over the part, but be careful not to spot or touch the surface while the vapour is upon it. As soon as the vapour has evaporated, apply the plumbago again, and the picture will soon become visible and dense. Then dust off all the superfluous plumbago, and varnish as usual.

By this means an infinite variety of pictorial effects can be produced cheaply and quickly without employing pictorial backgrounds behind the sitters; and, by a judicious choice of a picture, or part of a picture, the most artistic effects can readily be obtained; and the backgrounds of Reynolds and Lawrence, which are always beautiful and appropriate, may be employed and repeated *ad infinitum*. Skies can also be added to landscape negatives, and many of the troubles and annoyances of combination printing may be avoided by the employment of this process.

SENSITIVE SOLUTION.

Dextrine...	...	...	...	1	drachm
Sugar-candy	...	...	...	1	"
Bichromate of ammonia	...	...	...	½	"
Water	...	...	...	5	ounees

When all dissolved, filter for use.

MR. TILLEY'S COMBINATION PRINTING.

SIR,—In reply to Mr. Bovey, I am much obliged to him for his advice, and shall not fail to think the matter over before obtaining a patent for photographic combination.

My idea was that if I took out a patent, photographers could place at the foot of their cards the following, which might create more sale: "Patent Combination Print." Still, if I do not patent it, the words "Combination Photograph" could be used.

I would advise Mr. Bovey to work in quite a different way to find out the method by which I produce my combination. I think the plans Mr. Bovey has put forward are good, but I know they must all take too much time to compare with mine.

In answer to "W." of last week, I can only say that it is not the powder process, as I should think that would take more time than any plan Mr. Bovey has put forward. I claim for my process that of being the quickest, and, to compare results, I think it would be the best in preserving the entire portrait, even to the hair of the head and beard.

My process being so very simple in its working, it appears to be the more difficult to find out; and as "W." says it is tantalizing to wait the time I have stated, I must say that it is of no advantage to me to wait that time, but as I have given the offer, I must wait the time.—Yours respectfully,  
W. TILLEY.

### CORNWALL POLYTECHNIC EXHIBITION.

DEAR SIR,—If the catalogue of the Cornwall Exhibition is an authority, a second silver medal was awarded to a photograph entitled, "A Warwickshire Lane." Will your correspondent be kind enough to explain why he omitted this in his list?—Yours, &c.,  
E. S.  
*Leamington, August 31st.*

### Talk in the Studio.

CHARGE OF EMBEZZLEMENT.—A paragraph in a local paper states that Charles Stevens, a young man who presented a very respectable appearance, was charged by his employer, Mr. Howe, photographer, of Duke Street, Cardiff, with embezzling the sum of £1 4s., and purloining a number of photographs. Mr. Belloch prosecuted. The prisoner was employed by Mr. Howe as a negative printer, but he did not reside in the house. The evidence indicated that he had received several sums of money on behalf of his master, and Mr. Howe experienced considerable difficulty in getting him to prepare a statement of the amounts. Ultimately the accused made out a list of the sums received, showing a total of 24s.; and he then admitted that he had not the money with him. He left the house ostensibly for the purpose of getting it, but failed to return until the following morning, when, in a defiant tone, he informed Mr. Howe that he had spent the money. With regard to the photographs, it appeared that a married woman name Ballinger obtained the negative of her likeness from a young man formerly employed by the prosecutor, and gave it to the prisoner, who printed several copies without the knowledge of his master. In her evidence, however, Mrs. Ballinger stated that she intended to pay Mr. Howe himself for the photographs. The prisoner admitted the embezzlement, but asserted that he appropriated the money thinking that his master would deduct it from his wages. The prosecutor intimated that he merely wished to make an example of the prisoner, as he had been served in a similar way before, and had no desire to press for a vindictive punishment. The Bench sentenced the accused to a month's imprisonment with hard labour.

BRITISH ASSOCIATION.—The next meeting of the British Association will be held at Bristol under the presidency of Sir John Hawkshaw, C.E., F.R.S.

### To Correspondents.

C. A. B.—A cabinet lens—that is, one made especially by the opticians for cabinets—will answer for that size and for card heads and three-quarter-lengths very well. Both the makers you name have a high reputation, but we cannot advise you in this column as to which is best without assuming an invidious position.

J. C. S.—It is customary to send photographs to exhibitions framed and glazed. Such a course is necessary both for protection of the pictures and for effect in the exhibition.

H. L. (Bath).—Bichloride of platinum is used for blacking the brasswork of lenses and stops. Make a two-grain solution of bichloride of platinum, to which a few drops of the negative bath may be added. This must be applied with a camel's-hair pencil to the brasswork, which must be first thoroughly cleansed from dirt or grease. After the requisite effect is produced, rinse with clean water, dry, and polish with black-lead.

PRIMUS.—We should prefer plan No. 2, in which you will secure a better length and a good north light; but either plan will allow you to work pretty well. The chief difference will be in the facility for producing groups. With twenty-two feet length you will be able to produce full-length card portraits with the 2B lens of the maker you name, but you would not have length for groups of three or four persons full-length; whereas with the twenty-seven feet you will have no difficulty in getting the camera far enough back. 2. The maker will give you the best advice as to the two lenses you require.

RETAIL.—Write to Messrs. Marion and Co., of Soho Square.

F. T. D.—Minute white and yellow spots may proceed from various causes. Those on the cards forwarded to us a week or two ago were quite distinct in their character from those sent now. The former, we have no doubt whatever, were spotted by the bronze powder used in printing the mounting cards; whilst those sent now do not suggest such an origin. We cannot with certainty say the cause of the latter. They may proceed from minute air-bubbles formed on the surface in the fixing bath. Such minute bubbles are very apt to form under some conditions, and to adhere very tenaciously. The fact that some prints float, whilst some sink, would probably depend upon the presence of these minute bubbles. A print covered with them would be buoyed up and float, whilst a print without them would sink. Some samples of paper are more subject to such spots than others. We have known a sample of albumenized paper, good at first, gradually become subject to them, becoming worse and worse during six months' keeping. Probably some decomposition had been set up in the albumen surface. Keeping the paper in a damp place will tend to this decomposition. Your galvanized iron washing pan should not be used without being thoroughly varnished. 2. The imperfect working of an old bath is rather due to accumulation of contaminating matter than to the bath becoming weak or exhausted, and such a bath often gives irregular markings on the negative.

BRIGHTON.—There is not, properly speaking, such a thing as an instantaneous view lens, although there are various rapid working view lenses. Instantaneity depends as much upon the light and the subject as upon the lens. A good portrait lens is often used for producing instantaneous views. We cannot with propriety recommend any special lens in this column.

TWIN.—The addition of from half a grain to a grain of bromide of cadmium to each ounce of collodion will often increase detail and decrease density. But a great deal may be done by modifying other matters without touching the collodion. Slightly increasing the time of immersion in the silver bath will be useful, giving full exposure will be useful, and increasing the strength of the iron developer will be found useful. Use (say) a forty-grain iron solution with twenty minims of acetic acid to each ounce, and use a full quantity of it on the plate, so as to dilute the silver solution which is on the plate.

G. R. GILL.—Surface fog, which may be rubbed off with the finger, is very troublesome, and sometimes very difficult to trace to a cause, the more so as it may proceed from many causes. We can suggest some of the possible causes, but we cannot, of course, tell which cause is in operation in your case. Under certain conditions, the use of a newly mixed iron developer will produce the result, and a little age in the developer, or the addition of a little old developer, will cure it. Sometimes impure acetic acid in the developer will cause it. Sometimes the use of slightly decomposed collodion will cause it, when there is the slightest under-exposure. Sometimes light in the dark room will cause it. Sometimes the use of a nitrate bath which is charged with organic matter will cause it. There are also other causes, but it is probable that one of these causes is in operation in your case.

H. J.—The letter has been posted.

H. G.—We find that the revival of the column of NOTES AND QUERIES has given general satisfaction, and if all readers will contribute something of experience it will doubtless prove very valuable.

H. T.—We do not know of any one who repairs ebonite baths, and it is very doubtful indeed whether an ebonite bath can be repaired.

G. BRADAZON.—No; we think not.

W. CAMPBELL (Bengal).—The stamps sent were rendered valueless by the method in which they were forwarded, and were insufficient by sevenpence to cover the postage of the YEAR-BOOK.

Several Correspondents in our next.

## The Photographic News, September 11, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### HOW TO WRITE A GUIDE-BOOK—TINTED PAPER IN PORTRAITURE—TRANSPARENT PAPER FOR DRY PLATES.

*How to write a Guide-Book.*—One might soon become a Murray, or Badaecker, and write guide-books nowadays with great facility, with the aid of a good selection of the charming glass photographs prepared for the stereoscope by Léon et Lévy, of Paris. A gazeteer would furnish sufficient facts about population, history, and geographical situation, and then one has merely to sit down before one of those multiple stereoscopic stands, turn the handle, and look at the series of views that pass before your eyes. Suppose you want to write a book about the Rhine. Very good; you need not run off and purchase a ticket at Cook's, or study Bradshaw and Henschel, or spend time in getting up German-English conversations. You merely order in a series of views of such places you wish to visit, and put them into your stereo-machine, in the same order as they occur on the map. You sit down in front of the stereoscope, pen and paper on one side, and the gazeteer on the other. Here is a picture of Mayence to begin with: the country rather flat on both sides of the broad river, a large town of closely-built houses, a bridge of boats, and another for the railway, and tremendous fortifications everywhere. Turn the handle, and Bieberich appears: the mountains are a little nearer, and vineyards are seen on the hill slopes; that big building by the Rhine must be the Duke of Nassau's palace, which the Prussian Court now lives in occasionally. (*Nota bene:* as a traveller has just been looked up for a month, for saying that the German Emperor had forcibly taken possession of the castle, we take warning, and use a mild expression.) Then we proceed, and behold the long broad Rudesheimer mountain, covered with vines, that are seen stretching down to the very edge of the water; and opposite is the picturesque town of Bingen. Farther on, and we come to the first castle of importance, the Rheinstein. This castle is no longer a ruin, but a trimly-built edifice, standing on a cluster of sharp rocks, that pierce the dense foliage, &c. Really nothing would be easier than to go on in this strain, and pen a guide-book with the photographer's aid; and as the author would be sitting comfortably in his library all the while, untried by the many vicissitudes of travel, the chances are, he would produce a far pleasanter volume than the actual traveller. At any rate, we have shown the way to set about writing a book of travels, in case any of our readers might wish to try the experiment.

*Tinted Paper in Portraiture.*—The employment of tinted albumenized paper, which was never in high favour in this country, is general in some parts of Germany. For little pictures of some kinds (as, for instance, carte-de-visite bust portraits of ladies) the rose tint that is most frequently used is not objectionable; but in our opinion it is very rare that a portrait is really improved by printing upon coloured paper. In looking over a collection of portraits of this kind, you may pick out a few now and then where, as in the case of very hard negatives, the result has been improved by tinting; but the high lights suffer considerable degradation. While, however, the use of rose-tinted paper may be permitted under some circumstances for portraiture, there can surely be no advantage in applying such paper to the production of photographic landscapes, which are to be seen in many little German towns surrounded by a pink atmosphere. One soon becomes exceedingly tired of looking at pictures of towns and villages, rivers and mountains, all portrayed in a glow of red. If a blue or neutral tint were employed, the softening down of the photograph would be just, as that would be very welcome to travelling photographers. If the weight of the plates could be sensibly diminished, either by substituting some other material for glass, or doing away with the same

altogether, it would be an important boon to the amateur and travelling photographer. It is now three or four years ago since the Austrian Photographic Society offered a gold medal for a flexible and transparent film that might be employed as a basis for collodion; but as yet nothing has been discovered or invented which can take the place of glass. Gelatine seems quite unsuitable for the purpose, for employed in any way, whether rendered insoluble by chrome alum or by any other substance, it invariably swells on absorption of moisture. Mica can be employed, but it is too expensive, and, moreover, large sheets of it, clear and free from faults, would be most difficult to obtain. The problem seems an insurmountable one, unless we can come back to Talbotype and paper negatives, which would be feasible enough if only a nice uniform material could be secured. If paper-makers would only interest themselves in the matter, and experiment for the purpose of securing a firm transparent material, we cannot help thinking that an eligible photographic basis, just as effective, and the result would not be so unpleasant. Collections of pictures, both carte and cabinet size, are to be seen all printed on this rose-coloured paper, and some photographers print all their portraits upon the paper, without giving one an option in the matter. The Victoria cards (an intermediate size between carte and cabinet, which some time ago bade fair to become popular in Germany) seem to have made little way, and are nowhere to be seen; but a *format* (or style) larger than cabinet is making its appearance. This photograph is oval in form, and about a size and a half of cabinet. The price of cartes-de-visite in provincial towns in Germany appears to vary from eight to nine shillings a dozen, while cabinets fetch the same money per half dozen.

*Transparent Paper for Dry Plates.*—We have now brought dry plates to such perfection that there is really very little improvement to be effected, either in the preparation or development of sensitive films. They are quite sensitive enough for most purposes, and, as the plates suffer no deterioration by keeping weeks or months before development, it matters little how long they are preserved before being taken home to the studio and finished. There is one improvement needed, however; glass should be altogether discarded. Paper makers, unfortunately, will have nothing to do with gun-cotton, or pyroxyline pulp, notwithstanding that the wet fibre is perfectly innocuous; otherwise it is not unlikely that a right suitable paper might be made by employing ordinary pulp and gun-cotton pulp in equal proportions. Wet gun-cotton pulp is so non-inflammable that, rather than burn, it might serve to extinguish a fire quite as efficiently as a wet blanket; but, unfortunately, its name alone suffices to keep it out of a paper factory. A transparent paper termed *papier vegetal* is used by Leon Vidal for films which are superposed and seen by reflected light. This substance might, perhaps, be employed for negatives if it has no susceptible grain or fibre.

### FRENCH CORRESPONDENCE.

#### A PORTABLE CAMERA FOR DRY PLATES—THE COAGULATION OF ALBUMEN—NITRATE OF POTASH IN THE SILVER BATH—DAVANNE ON PRINTING AND TONING.

I HAVE lately had the pleasure of seeing a very ingenious apparatus, which is particularly adapted for use by amateurs and tourists. It is destined for employment with dry plates, and the whole amount of baggage may be included in a box of a few centimetres cubic measurement. The complete apparatus (to which the inventor, Dr. Ernest Tandaze, has given the name of "Scénographe") consists, firstly, of the camera and lens; secondly, the base; thirdly, the stand in the form of a walking stick; fourthly, the dark slide; and, lastly, the focussing screen.

The camera, as soon as ready for the operation, has quite the appearance of an old stereoscope, the sides of which are of black linen. It is composed of two frame-

works of acacia, or oak, or any other wood, covered with a bag of black or green silk, impenetrable to light. The smaller frame placed in front carries the lens, which is mounted upon a base, which may be moved to the right or left, according as a stereoscopic or album picture is to be produced.

This frame, which when shut up occupies only the space of the two frames, is pulled out, and becomes rigid as soon as you desire to operate, two movable slides of wood, above and below, stiffening it. A little plumb and line attached to the top slide demonstrates whether the apparatus is level or not. The second slide, which is under the camera, is furnished with a screw-plate, to which the stand is fixed. An arrangement allows of the taking of broad pictures or upright ones.

The camera is automatic—that is to say, its length is calculated so that the apparatus is in focus for objects situated at twenty-five metres, and beyond. When the object is at a lesser distance, then the lens must be focussed by the rack-and-pinion. The base, or support, is composed of two discs of wood screwed to one another and forming a sort of box in which there is a sphere, also of wood, furnished with a screw, which enters into the screw-plate above referred to, and the apparatus is by this means rendered mobile, or immobile, according as the screw is tightened or loosened. Below are three holes, in which the three legs of the stand are fixed. The legs are tubes fitting one in the other, the smallest being of copper and the other two of wood; when it is desired to use the stand, the cap of the stick is simply unscrewed, and the tubes fitted into the holes at the basis of the camera.

The dark slide is a frame of light wood, with a double slide of thin, hard cardboard; it holds two dry plates separated from one another by a sheet of opaque paper, and its dimensions are eighteen by thirteen centimetres, and its breadth twelve millimetres.

Such is a brief description of the Scénographe; and I may add that all the portions are so finished as to leave nothing to be desired in regard to securing perfect results. Finally, the price is so moderate that it may be purchased with the most moderate purse. It is certainly very superior to the Dubroni apparatus, which has been much employed by beginners, &c.

M. Quiquerez, whose name I have already mentioned in connection with the coagulation of albumen, has addressed me some further observations of an interesting nature upon the same subject. He persists in believing that a weak alcoholic bath has an action upon the albumen; he calls to mind, among other means of coagulation, that proposed some time ago by the Abbé Laborde, and which consisted in floating albumenized paper (the albumenized surface uppermost) upon a hot water bath of 100° Centigrade. He thinks that paper treated in this way would have the same defects as that coagulated by steam.

A twenty or twenty-five per cent. silver bath does not coagulate albumen entirely, for in a short time it begins to become yellow, and to emit a fetid odour, due to the albumen dissolved in it. Quiquerez employs a nitrate of potash bath, and, like many other operators whom we could cite, including M. le Comte de Courten, he is highly satisfied with it. It must not be forgotten that when the paper is treated, not only is chloride of silver formed by double decomposition, but a very sensitive product to light besides—albuminate of silver. M. Quiquerez thinks that nitrate of potash has the effect of facilitating the formation of chloride of silver, by rendering the film of albumen more permeable without at the same time dissolving it. By softening the surface of the paper it renders it more easily sensitized; it should be remembered that Dr. Van Monckhoven, in his treatise on photography, advocates keeping the paper in a moist place, so that the film may not become too much dried.

Not only, according to M. Quiquerez, has nitrate of potash a softening effect upon albumen, but it acts at the

same time as a preservative against putrefaction, and the bath wherein it is employed has no bad odour, even after long usage. It is always a good precaution to keep the bottle containing the bath in full sunlight, for, admitting that the albumen is perfectly coagulated, the bath is still liable to become contaminated with dust and dirt particles.

Any tint that may be desired can be secured on toning with the bath in question. M. Quiquerez does not think that ammonia fuming is indispensable, but the pictures print and tone more readily if ammonia be used. It is, besides, a process so simple that there is no reason for omitting it.

It is known that chloride of silver absorbs ammonia in large quantities, so that the fumed paper is in the same state as one prepared with a bath of ammonia-nitrate of silver; and it is well known that this compound has often been recommended by skilful experimenters who desire rapidity and softness.

M. Quiquerez forwarded in his letter some prints, the paper of which was sensitized upon a five per cent. nitrate of silver bath, containing as much as eight per cent. of nitrate of potash besides. The paper, which is highly albumenized, has lost nothing of its brilliancy. The photographs were not intensified in any way, and yet they are very vigorous.

In reference to this subject I may quote a passage from M. Davanne's text-book, adopted at the *Ecole des Ponts et Chaussées* at Paris. "The paper is prepared by floating for some instants upon a bath of albumen, to which chloride of sodium has been added in a quantity that varies from two to three per mille to two or three per cent. When in a dry state it is ready for use. The paper is sensitized upon a silver bath, the concentration of which varies from eight to fifteen per cent., according to the quantity of chloride in the albumen. If the bath be too strong for a slightly salted albumen paper, the liquid runs, or dries in streaks and drops of an oily character, and forms stains or patches. The most useful formula is:—

Crystallized nitrate of silver... 10 grammes  
Distilled water... .. 100 cub. cents.

A few drops of carbonate of soda solution to produce a permanent white precipitate.

"The sensitive film upon this paper is formed of complex products: chloride of silver, a sensitive compound of albumen and silver salts, a combination similar to starch, and free nitrate of silver. All these substances aid in the formation of the image. Alone, they give but inferior results; but together they furnish very fine impressions. The toning bath is made up of—

Water ... .. 1,000 cub. cents.  
Double chloride of gold and  
potassium ... .. 1 gramme  
French chalk, about ... .. 5 grammes.

This solution, which has a slightly yellow tint, should be bleached by the action of light, or by preservation for some time. It is well to prepare it and expose it to daylight for at least three hours before use. The object of bleaching is to transform the greater part of the perchloride of gold into protochloride; the perchloride reddens the print by depositing a quantity of gold, inferior to the quantity of chloride of silver formed, whilst with the protochloride the deposition is gradually by molecules. The period of immersion in the bath depends upon the tone that it is desired to obtain, and upon the concentration of the bath. A sojourn too prolonged makes the picture dull and flat.

ERNEST LACAN.

## THE PRACTICAL PRINTER IN AMERICA.

### VII.

#### DURABLE SENSITIVE PAPER.

A CHAPTER devoted to the various modes of preparing durable sensitive paper is less practical than the bulk of Mr. Hearn's work, as it chiefly consists of a resumé of the

modes which have been proposed, without much of his own experience. Our readers are familiar with the modes of using citric and other acids, washing the paper after sensitizing, using carbonate of soda for preserving the sensitive paper, and we need not repeat them here. We append, however, his remarks on washing sensitive paper:—

“*Washed Sensitive Paper.*—Paper sensitized in the usual way, and then washed, acquires keeping properties similar to that floated on a bath prepared especially for the purpose. The paper, when washed, should never be *soaked* in a bath of water, but only drawn through it *once*, and should not be permitted to remain in it more than one second longer than is really necessary, or it will surely make flat prints. The paper is floated upon the silver bath as you would do for ordinary sensitizing, and when drained sufficiently it is drawn through a lukewarm bath of pure water, permitted to drain again, and then hung up to dry.

“Long sensitizing on a strong bath is necessary for the success of the washed paper, and the water should be fresh every time you wash a sheet of paper. The used water can have the silver in it thrown down in the form of a chloride by sprinkling a little salt in it.

“An excellent bath for the paper that is destined to be washed is made as follows:—

Nitrate of silver ... ..	60 grains
Nitrate of ammonia ... ..	30 „
White sugar ... ..	3 „
Pure water ... ..	1 ounce.

Make *neutral* (*i. e.*, neither acid nor alkaline) with bicarbonate of soda; float two minutes, let drain, and then pass the paper quickly through a citric acid bath of one grain of the acid to the ounce of pure water. Dry thoroughly, and pack away the paper in the dark without fuming, being careful not to expose it to the light.

“This paper will keep white for months if it is packed between blotting-paper, in a box which is made air-tight. To preserve the paper for a long time it is necessary, first, to prevent *white* light from ever striking the surface until it is to be printed; second, to always pack the paper in a dark room, and the packing should be so conducted that the paper in the boxes should be perfectly protected from the air; third, the packed boxes should be placed in a cool and dry place, and not in a place where the atmosphere is apt to be changeable.

“The paper should be fumed from twenty to twenty-five minutes, when about to print it, and chloride of lime should be in the fuming box at the time, to absorb the moisture of the ammonia, and to keep the paper white, for preserved sensitive paper turns quite yellow while being fumed.

“Paper is often—instead of being drawn through water—floated upon a bath containing alum in the proportion of four or five grains of alum to the ounce of water, or on a bath of water in which there is a little hydrochloric acid. There is some fault found with the acid on account of its being too insensitive. Objection is also raised to the simple citric acid; but in the latter case, instead of its being too insensitive, it is the reverse. In the case of the citric acid, if the number of grains of the acid to the ounce of water is not too large it will work well.

“Durable sensitive paper, whether washed or not, should always be fumed before use.

“*Toning.*—For good success at toning the citric acid (durable) paper, whether the acid is in the composition of the printing bath, or whether the paper is drawn through or floated upon a bath of diluted citric acid, the washing before toning should be comparatively very slight; and although the paper may be red, you should soak the prints in a very weak bath of acetic acid and water, a minimum of the acid to the ounce of water, for five minutes, and then rinse well. For toning citric acid paper have the bath very alkaline, and if the prints should refuse to tone nicely, drop in about six to eight minims of a plain silver solution,

ten grains strong of the silver to the ounce of water. Stir well, and let stand for five or ten minutes.

“Warm the toning solution quite warm, and then allow it to cool to a lukewarm state before using. The ordinary toning bath can be used very successfully in toning the durable paper; indeed, there is no necessity for any other bath than those which will be given in a future chapter.

“The alum bath paper will tone more easily than the citric acid, and in toning this paper the toning bath need not be so alkaline.”

(To be continued.)

### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

1.—At a meeting of the British Association held in Manchester in the autumn of 1861 I exhibited some photographs of spectra from the spark obtained between wires of different metals by means of an induction coil. Upon this occasion a hollow prism filled with bisulphide of carbon was employed, because, owing to its great dispersive power, it furnished spectra in which the lines under examination were more widely separated, and exhibited with greater distinctness than by any other medium in ordinary use.

The great prolongation of the more refrangible portion of the spectrum beyond the part visible to the unaided eye led me to believe that bisulphide of carbon was a material which exerted but little absorbent action upon the chemical rays. Subsequent experiments have, however, convinced me that this opinion was erroneous, and have rendered it necessary to modify considerably the conclusions deduced from those experiments.

2. At the time that that paper was written, I believed that the photographic effects produced by the electric spectra of all the metals furnished results in a great degree similar to each other, if not actually identical. This, it will be seen from subsequent statements, is correct so far as the fact of the similarity in this portion of the spectra is concerned, but is erroneous as regards the general conclusion deduced from it. During the past winter I have renewed these experiments, substituting a quartz train for glass and bisulphide of carbon, and have chiefly used a fine quartz prism, kindly lent to me by my friend Mr. Gassiot. The refracting angle of this prism is about 60°; its faces are about 2 inches long and 1½ inch broad, and are so cut as to furnish a singly refracted beam for the medium rays, by transmitting it along the axis of the crystal. It is well known, from the experiments of Prof. Stokes† and M. E. Becquerel, that quartz is remarkable for its transparency to both fluorescent and phosphorogenic rays of high refrangibility. It was soon evident that the absorbent action of the bisulphide was far greater than I had imagined, and that, in reality, the spectrum which it transmitted was composed of rays which did not extend beyond one-tenth or one-twelfth of the entire length of the spectrum obtained by the use of a quartz train.‡

\* We have had frequent occasion to refer to the late Professor Miller's valuable paper on the photographic transparency of various bodies, and have also often had enquiries in reference to the subject; and although we printed it in abstract at its original date, we think it worthy of preserving in our pages at length as published in the “Philosophical Transactions,” 1863.

† Phil. Trans., 1852, p. 540.

‡ The absorptive power of the bisulphide for the chemical rays was, however, noticed by M. E. Becquerel as far back as 1843, as I find by again referring to his paper (*Annales de Chimie*, sér. 3, vol. ix, p. 301). In this paper, M. Becquerel describes the absorbent action of various solids and liquids upon the chemical rays, but, from having used solar light, he failed to remark the great difference between the absorptive powers of quartz and glass. Although he used prisms of rock-salt, rock-crystal, and alum, his results do not indicate the real difference in their absorptive power; and, as in all his experiments on liquids he employed a vessel with tint-glass sides to hold them, his conclusions are vitiated by the same error which affected my own earlier inquiries on the subject.

3. The dispersive power of rock crystal is, however, comparatively low, and the difficulty of obtaining with it a spectrum free from the effects of double refraction through its entire length is great, so that it appeared to be worth while, as a preliminary inquiry, to ascertain whether any singly refracting medium could be procured better adapted to researches of this nature by sufficient permeability to the chemical rays, and by tolerably high dispersive power. Although no material on the whole preferable to quartz has been found, the investigation gave results of considerable interest.

4. Before proceeding to detail these results, it will, however, be convenient, as several distinct subjects will be discussed in this paper, to state the order in which I propose to arrange my remarks, and the heads to which they will be referred.

I shall commence with—

1. The absorption of the chemical rays by transmission through different media.

a. By transmission through solids.

b. By transmission through liquids.

c. By transmission through gases and vapours.

2. The absorption of the chemical rays by reflection from polished surfaces.

3. The photographic effects of the electric spectra of different metals taken in air, including—

a. Pure metals.

b. Alloys.

4. Photographic effects of electric spectra of different metals produced by transmitting the sparks through gases other than atmospheric air.

5. The general results of my experiments upon the absorption of the chemical rays are the following:—

1. Colourless bodies which possess equal powers of transmitting the luminous rays vary greatly in permeability to the chemical rays.

2. Diacronic solids (that is to say, solids which are permeable to the chemical rays) preserve their diacronic power, both when liquefied, and when converted into vapour.

3. Colourless solids which are transparent to light, but which exert a considerable absorptive effect upon the chemical rays, preserve their absorptive power with greater or less intensity, both in the liquid and the gaseous state.

Whether the compound be dissolved in water or be liquefied by heat, these conclusions are equally true as regards liquids. Water is perfectly permeable to the chemical rays; and this circumstance, conjoined with the fact that in no instance does the process of solution seem to interfere with the special action of the substance dissolved upon the incident rays, render it practicable to submit to trial a great number of bodies which it would otherwise be impossible to subject to experiments of this nature, owing to the extreme difficulty of obtaining them in crystals of sufficient size and limpidity.

(To be continued.)

## ON THE OPACITY OF THE DEVELOPED PHOTOGRAPHIC IMAGE.

BY CAPTAIN ABNEY, R.E., F.R.A.S., F.C.S.\*

IN a series of pictures of the sun which have lately been taken by photography I found the opacity of the image by no means varied directly as the time of exposure. This caused me to institute an inquiry into the relation of time of exposure and intensity of light on the one hand, and the resulting opacity of the image on the other.

Primarily it was necessary to obtain some known gradation of intensity of light, and then to measure the resulting opacities caused by it on the photographic plate. The gradation was obtained by causing a "star" to revolve

rapidly round its centre. The "star" was cut out with great exactness from white cardboard, and made with eight "points." The curve of each point was made to take the form of a portion of an equiangular spiral. By this means an arithmetical progression of white was obtained when the star was made to rotate. When revolving in front of a black background, at two inches from the centre of the card (and within that distance), pure white was obtained; whilst at fourteen from the centre pure black was obtained. The black background employed was of such a dead nature that sunlight gave no appreciable shadow on it when an opaque body was placed before it.

The star was made to revolve at the rate of fifty revolutions a second. In some cases a dead-black star was made to rotate before a clear sky, the only access of light being through the openings of the points.

Plates were exposed on this object, the negatives being obtained by the ordinary wet process, with simply iodized collodion, an eight per cent. nitrate of silver bath, and four per cent. iron developer. The strength of the developer was afterwards varied; but for the purposes of these experiments any variation was excluded. Other negatives were obtained on dry plates made with bromized collodion—a sixteen per cent. nitrate of silver bath, albumen preservative (washed off, after application, as far as possible), and alkaline development of one particular strength. By alkaline development, as is well known, the bromide of silver is reduced to metallic (or oxide of) silver *in situ*, no free nitrate of silver being applied to the image during development. The opacity of the image obtained by this method is particularly adapted for giving the necessary means of measuring the action of any relative intensities of light acting on the silver for any time.

In order to determine the opacities of the image, it was necessary to obtain some standard scale with which to measure. The ordinary method was tried without success, the image being "matt," or only translucent. Failure with them was inevitable. After various experiments with coloured gelatine wedges, I determined to use coloured glass wedges, and, owing to the kindness of Mr. Browning, obtained three smoke-coloured ones, corrected for refraction by crown glass. These, in varying combinations, have given me everything that could be desired. The mounting I adopted for them is as follows.

A is the wedge in position; B a space in the frame E, in which any glass whose opacity is to be measured is placed; C a slit; and D a fixed scale dividing the wedge into arbitrary divisions. In actual use the whole of the frame was glazed with finely ground glass, the slit being next to it, and the wedge against that again. When measurements of opacity were taken, the glass to be tested was placed in B, and a light placed at a known distance behind the slit. Great care was taken to ensure the equal illumination of C. The length of the wedges are severally 6.5 inches.

Fig. 1.

They do not give a zero of absorption at their thin ends, it being found necessary in grinding to have an appreciable thickness. I was enabled to calculate the relative absorptive values of each wedge, and the following table will give an idea of the degree of accuracy with which they were scaled. The values are given in lengths of a half-inch scale, starting from the calculated zero of the wedge which

\* *Philosophical Magazine.*

I have called A. Each of the wedges was reduced to the same scale. The numbers refer to different opacities which were measured. A mean of six readings was taken in each case, and in no instance did any reading vary more than .15 from the mean.

	A.	B.	C.
No. I. ...	7.15	7.13	7.13
No. II. ...	10.21	10.20	10.18
No. III. ...	12.44	12.45	12.41
No. IV. ...	17.60	17.50	17.52
No. V. ...	18.60	18.52	18.52

From careful measurements, it was found that the coefficient of absorption for each unit of scale of wedge A, for the light with which the measurements were taken, was .192.

The photographs of the rotating star were taken of the full size of the original, only half of the disk being, in some cases, on one plate. Strips were cut from these negatives, one edge always passing through the centre of the image of the star. The relative transparencies of every  $\frac{1}{4}$ " or  $\frac{1}{8}$ " were obtained by comparison with the wedges. From these values the accompanying curves (fig. 2) have been formed, the ordinate being the transparency, whilst the abscissa is a measure of the intensity

Fig. 2.

A and B are the curves given by the images on the dry plates.  
 C and D are the curves given by the images on wet plates.  
 The dotted lines indicate the line whose ordinates give an arithmetic progression of transparency, E F being unity, or transparency.  
 F G represents the length of the strips examined, and therefore the varying intensity of light, F being zero, and G the maximum.

of the original reflected light. Only four results are shown—two obtained by wet, and two by dry, plates. About thirty were measured with almost identical results.

Each strip was compared with the wedge by daylight, and also by an artificial monochromatic light. The results obtained by the one were nearly proportional to those obtained by the other; hence, only one curve for each strip is given, and this was obtained by the latter light. To guard against a false ratio of intensity of light due to the lens, negatives of the star were taken at different parts of the plate, and a mean taken. As the

lens used was non-distorting, and of long focus, the edge and centre of the plate, when directed towards the sky, or on a uniformly white surface, had sensibly the same illumination. Each portion of the strip cut from the negative whose opacity was to be compared was placed above the wedge, at B, and opposite the slit C. These were clamped together, and moved till light from behind, shining through the slit, and through the image and the wedge respectively, appeared of the same brightness on the ground glass. The position of the slit in regard to the scale was noted, and the intensity of light transmitted calculated by the ordinary formula. Each strip was compared six times—three times by myself, and three times by an assistant. A mean of the six readings was taken as correct.

Regarding the curves given by the dry plates, if we suppose that varying intensities of light cause a corresponding reduction of the bromide of silver after development, it can be easily demonstrated that the intensity of light passing through the image, after clearing away the unaltered bromide, would be

$$I' = n \cdot e^{-kI} \dots \dots \dots (\alpha)$$

where  $n$  and  $k$  are constants depending on the thickness and opacity of the bromide film, and  $I$  the intensity of the light producing any one part of the image—that is, on the supposition that the image is formed of matter continuous, but of varying density. This is not the case; but there is an approximation to it. Under the same supposition we can assume that there is a function of time into a function of intensity of light acting on an infinitely thin layer of the bromide of silver which will cause an entire reduction of the bromide on development; this we might call a state of saturation. In the image of the star there may be some point where the upper layer of bromide (of infinite thinness) is saturated. From that point, along the image to be produced by the higher intensities, the whole surface is saturated, and the saturation must gradually approach the bottom surface. From the point where the whole depth of the layer is saturated, along the image to be produced by still higher intensities, there can be no further change. Here it can be demonstrated that, between the two points above alluded to, the curve should have the form

$$I' = pI^{-q}e^{-rI} \dots \dots \dots (\beta)$$

where  $p$   $q$   $r$  are constants, and  $I$  is the original variable intensity producing the image. From the last point parallelism would result, and  $q$  would become a constant. Theoretically, then, the measure of the varying transparency would be compounded of  $(\alpha)$ ,  $(\beta)$ , and a straight line.

The curves shown above lead us to suspect that this is the practical result of increase of intensity and time. From other experiments, however, I am inclined to think that, even where there is no saturation, the relation between time and intensity is not so simple as has hitherto been imagined. When light actually reduces bromide without the aid of a developer, a compound curve, somewhat similar to  $(\alpha)$  and  $(\beta)$ , will result. In collodion-chloride printing on glass a like result would occur. Presumably the same also occurs when printing on albumenized paper. The curves deduced by experiment, and also from calculation, show the reason why, in a negative, the detail in the shadows and highest lights is more difficult to render faithfully than in the half-tones. They may also show why, in a print, the details in the first-named portions are liable to be obliterated, even should they be well defined in the negative.

The curves measured from the dry plates show that bromide of silver is less sensitive to low intensities of light than is the iodide.

The action of different strengths of developers I propose to treat of in a separate communication; as also the relation between time of exposure and intensity of light.

## LANDSCAPE PHOTOGRAPHY FOR PORTRAITISTS.

THERE is a very large section of the photographic community, consisting of the majority of professional portraitists, who have probably rarely or never produced a landscape, and who, not for lack of photographic skill or knowledge, but simply from absence of experience and lack of suitable appliance, would find the task a troublesome one if they were called upon, for business or pleasure, to make the attempt. One or two brief hints as to the modifications in apparatus, materials, or operations, which may be easily made conducive to success, may be of interest and service to such of our readers as belong to the section of the community we have indicated.

The conditions of portraiture and landscape work are in many respects essentially different, and the photographer solely familiar with one branch rarely succeeds at once with the other. Our aim here is not to enter into a consideration of the best apparatus and the best preparations for securing the highest success in landscape work, but simply to suggest to the modestly equipped portraitist in what manner he may best set about producing a landscape should choice or necessity place the task before him.

As regards apparatus. In many portrait establishments there are, of course, only portrait lenses; and these, although not the best for landscape work, may be made to answer very well. The ordinary portrait lens with a small stop will give very good results. The size of the stop must be determined by an examination of the image on the ground glass; but as a rule it will require to be much smaller than is usually necessary in studio work; but at the same time we should recommend working with a stop as large as possible consistent with definition. In focussing, the studio experience of the operator will not take him far enough. There are two points to which attention must be given on the ground glass: first, that sufficient definition is secured at the margin of the picture, as well as in the centre; and second, that the various planes of the picture, foreground and distance, are sufficiently defined. It is better to focus on some principal object in the foreground, and the size of the stop must then be reduced until the various planes beyond are sufficiently sharp. In using the term *sufficiently* sharp, we assume that the operator is familiar with all the term involves. It is not necessary nor desirable that the middle distance and extreme distance should be as sharply defined as foreground objects, nor is it in many subjects as important that the margin of a picture should be as sharp as the middle portions, in which the focus of interest as well as definition should be found. One special fault of the

portrait lens is, that it is more difficult to spread definition and illumination with it than it is with a single landscape lens. With a portrait lens there is a concentration of illumination and definition towards the centre; with a landscape lens the illumination and the definition are less intense and more evenly diffused. The front lens of many portrait combinations makes a capital landscape lens, and in some cases it is so arranged that, on unscrewing and removing the back lens of the portrait combination and placing the front lens in its place, with the inside surface turned to the view, it is suitably fitted for use as a landscape lens. The focal length of the front lens of a quarter-plate portrait combination is often about twelve inches, and answers well for whole-plate views. In using a single view lens there are a few points to be remembered which are not always familiar to the portraitist. A stop of much smaller aperture should be used than is almost ever used in the studio. The aperture should rarely be larger than one-twelfth of the focus of the lens. Thus, in using a lens of twelve inches focus, the aperture should not exceed an inch, and in many cases, to secure good results, it may with greater advantage be about half an inch. The stop should, as a rule, be placed about one-fifth of the focus in advance of the lens. The nearer the stop is placed to the lens, the larger will be the field of illumination, and the less the amount of barrel-shaped distortion always present when a single lens is used; but the marginal definition will be rendered less perfect, and the curvatures of field will be increased. Thus, if it be necessary to use a single lens for interiors, the stop may with advantage be placed near to the lens, as a curved field is in such a case an advantage, and absence of barrel-shaped distortion another advantage. But where a flat field is of importance, the end will be gained by removing the stop as far from the lens as convenience will permit.

A landscape camera of some kind will, of course, be desirable, for convenience, and a portable camera stand; but in their absence, for an occasional essay, the portraitist must make shift with the most portable appliances in this way which he can command.

It is probably in the use of materials, formulæ, and manipulations generally, that the photographer solely used to studio work will find himself most at a loss. At the outset he should remember that as a rule more density and more brilliancy are required to give fine landscape prints than those in the present day commonly produced in portraiture, which, for the best results, are usually thin and delicate. It is desirable that the collodion should have more body; and whilst the same silver bath may be used, the developer should be weaker and more acid. We may here quote some good remarks on the subject by Mr. Gihon, a skilful photographer in Montevideo, writing to our Philadelphia contemporary. He says:—

"The thin delicate negatives that every advanced operator prides himself upon producing in atelier work are most unsuitable for landscape purposes, and he who takes the field provided with the materials that he has used for portraiture will soon find that modifications are necessary. Collodion, bath, and developer, each and all, have to be altered. With collodion, I have always maintained that excessive nicety in choice and proportions of sensitizing salts is not of the first importance. The quantity and character of the cotton that is added to the ether and alcohol, and the relative proportions of each of the latter, have always presented themselves to me as matters worthy of more attention. I advance it as a rule that nicer distinctions in the printing capacities of a negative can be made by judicious selections of gun-cotton than by the same amount of experiment with different iodides and bromides."

He recommends using about double the quantity of cotton for landscape work that is used for portraiture; and to use a bath forty-five grains strong. In reference to developer he refers to a formula published by us some

years ago, and says:—"Late constant use leads me to recommend it in the strongest terms.

Protosulphate of iron	...	...	3 ounces
Sulphate of copper	...	...	1 ounce
Water	...	...	80 ounces
Glacial acetic acid	...	...	3 "
Alcohol	...	...	3 "
Ammonia...	...	...	100 drops

This developer improves with some little age, and can be used with the utmost safety in relation to any fogging propensities. Its action upon a well-timed plate is all that can possibly be desired."

A more simple developer, which we found capital for landscape work, is as follows:—

Protosulphate of iron	...	...	20 grains
Acetic acid	...	...	40 minims
Liquid ammonia	...	...	1 minim
Water	...	...	2 ounces

This develops somewhat slowly, but gives delicacy, brilliancy, and force. As we have already occupied sufficient space, we must refer again to the subject in our next.

AMERICAN CORRESPONDENCE.

ALUM FOR ELIMINATING HYPO—MR. HEARN'S FORMULA—A GOOD IDEA.

*Alum.*—Nothing is more curious than to get in a assemblage of men and women and quietly watch their actions—in a convention, for example. Some most curious things occur. Matters of no real importance at all will be brought up and discussed at great length, and a consequent loss of time, each one insisting upon saying his say, while matters of vital importance are scarcely noticed. Such a study is our National Photo. Convention. What follows will give you an illustration. Mr. William H. Sherman, of Milwaukee, Wisc., is one of our most diligent and enlightened experimentalists, and at our Buffalo Convention gave us the vermilion toning bath. He is always a lively correspondent. The following I glean from one of his recent letters on the subject of *alum*. He says:—

"It was announced before the National Photographic Association at Chicago, by Mr. Clemons, that he had discovered a simple process by which the hyposulphite may be eliminated from silver prints, after fixing, in the short time of eight minutes. All that is required to insure this most important result is to immerse the prints, directly from the fixing bath, in a saturated solution of alum, whence, after removal and rinsing in a few changes of water, the work is accomplished, which otherwise requires much labor and many hours' time, and is even then but imperfectly performed.

"I am unable to say which was most to be wondered at, on that memorable occasion, the comparative lack of enthusiasm with which the announcement was received, or the quiet and unobtrusive manner in which the discovery was made known. But more wonderful and surprising than either are the simplicity and completeness of the process. Here is the problem which has baffled the enquiry of investigators ever since it became known that silver prints would fade, until not only is the possibility of their permanence well nigh despaired of, but the public are beginning to intimate, in a manner not to be misunderstood, that something must be done to remedy the difficulty. The need of some safe and sure method of removing the hyposulphite from the prints is pressing. Practically to accomplish this by washing is impossible. If the prints are washed rapidly, some of the hypo remains, and its presence may be detected by a suitable test. If they are washed a long time, they at length turn yellow in the water, probably by decomposition of hyposulphite and liberation of sulphur. It remains, then, to choose one or the other horn of the dilemma. One is to remove the prints from the water in a short time, with their brilliancy unimpaired, but with hypo in them; the other is to wash them until, if there is no hypo in them, they are more or less yellow with sulphur from decomposed hypo. Of the two the former is, unquestionably, the better choice. In either case they will fade.

Is it possible that photographers are so indifferent to the future fate of their productions as to fail to appreciate the discovery that

enables them, in so simple and easy a manner, to remove the cause of the mischief, which, if not remedied, will sooner or later seal the doom of silver prints? The hypo all removed and the washing completed "in eight minutes!" It can be done. There is no mistake about it. There is no longer even the shadow of an excuse for photographers palming off pictures with hypo in them. But little water is needed for the prints after they have been in the alum. One or two pails full will answer if it happen to be scarce.

"As to the alum solution, it may be used over and again. Mr. Clemons did not tell us this, but it is so, nevertheless. Take a strong barrel with wooden hoops (say a whisky barrel), and into it put a bushel of alum. Fill the barrel with water, and stir with a broom-handle until no more will dissolve. This will last your lifetime. After fixing, put your prints from the hypo right into the barrel; or, if more convenient, drain off the hypo, and then dip out enough of the alum-water in a wooden bucket, and pour over the prints. After stirring and soaking the prints the alum may be poured back, and stirred up with the rest. It may then be left to settle.

"It will be observed, after immersing the prints in the solution of alum, that the liquid will assume a milky appearance, and the sense of smell will easily detect the odor of burning sulphur. The former is sulphur from the decomposed hypo, and the latter is sulphurous acid from the same source. After the prints are removed from the alum water and rinsed, dry them thoroughly, and burn them.

"The alum 'eliminates' the hypo, by converting it into sulphate of soda, sulphur, sulphurous acid, and water. This completely disposes of the hyposulphite. The sulphur being insoluble, the portion in the prints when liberated by the alum remains in the prints. This is the chief objection to Mr. Clemons' process. The sulphur must be 'eliminated,' or the prints will fade. This may be said to be an established fact. Sulphur, in a state of minute division, especially when associated with organic matter, oxidizes in the air. This, it is known, will cause paper to become rotten, and this is believed to be the cause of the fading of silver prints when a trace of hypo is left in them. Whatever method is employed to remove the hypo from the prints, it is essential that the process by which the elimination is effected do not introduce some substance or substances equally or more injurious in the place of that which is eliminated."

*Mr. Hearn's Formula.*—I am glad to notice the value you set upon Mr. Hearn's new book, "The Practical Printer." It is just as good as you say it is, and upon a subject which photographers need to study diligently. Still, you have given your readers so liberally of the contents of the new book, that I need not dilate upon its excellences here. Mr. Hearn has supplied me for publication here (and I send you an early copy of it) his "formulae in a nutshell." Of course, it will not be understood that this is all he teaches in his capital work. It is only the skeleton, and the book fills in all the interstices, with most careful attention to details, so that the result is full, and round, and rich with valuable information. But here is the "Nutshell."

"SILVER BATH.

"I place a sufficient quantity of the N. P. A. extra brilliant Dresden pink paper, for the next day's use, over-night in a close box, on the bottom of which I place a tray of fresh water. This dampens the surface of the paper, and makes it take very readily to the solution when floated.

"Make up a solution as follows:—

Nitrate of silver	...	...	...	45 grains
Nitrate of ammonia	...	...	...	45 "
Alum	...	...	...	1 grain
Distilled water	...	...	...	1 ounce

"Make the bath quite acid with nitric acid, C. P., and then perfectly neutral by the addition of liq. ammonia. Place a lump of camphor in the solution, and it will always prevent blistering. Float the paper sixty seconds, and draw it over a smooth glass rod. Dry quickly, and fume ten minutes. Print about two shades dark.

"ACIDIFYING SOLUTION.

Lukewarm water	...	...	...	1 gallon
Acetic acid, No. 8	...	...	...	½ ounce

"Acidize fifteen minutes; keep moving all the prints constantly. Pour off this water and save it, also the next rinsing water. Wash

in another fresh bath of water five minutes, and they are ready for toning.

"TONING BATH."

Acetate of soda ... ..	15 grains
Chloride of soda ... ..	10 "
Chloride of gold ... ..	1 grain
Filtered rain-water ... ..	15 ounces

"This bath ought to be a week old for stock, and every day, about two hours before toning, make up in the same proportion as above a fresh lot of sixteen ounces, and mix the two together. The prints will tone in about ten minutes, which is plenty quick enough for me. Tone a little purple. Place the prints, as soon as toned, in a bath made as follows:—

Sat. sol. alum ... ..	16 ounces
Water ... ..	1 gallon

"Remove the prints, when ready for fixing, from this bath into a hypo bath made as given below:—

Hyposulphite of soda, sat. sol. ... ..	1 ounce
Water ... ..	12 ounces
Bicarbonate of soda, sat. sol. ... ..	1 ounce
Chloride of soda ... ..	½ "

"Fix fifteen minutes, weaken one-half, and fix five minutes longer, and then weaken to about as near as you can calculate the density of the salt solution, which is made as follows:—

Chloride of soda ... ..	1 ounce
Water ... ..	1 gallon

"Let the prints remain in here about ten minutes, and then weaken this to about one-half of its former density, and let them remain five minutes longer; and now finally let this salt-water bath be weakened to the density of fresh water, and then remove them to the washing-tank, and wash them well before you leave them for the night, as this is very important. Three or four hours' washing is sufficient, when the plates are soaked in a salt-water bath after fixing.

"Rinse the next morning in pure filtered rain-water, so as to remove all iron-rust from the prints, and mount damp."

*A Good Idea.*—That is a good idea of yours, to suggest to your society the offering of a medal to American photographers. I am sure it will bring more responses than our offer to England does.—Truly yours,

Philadelphia, August 26th.

EDWARD L. WILSON.

### GERMAN CORRESPONDENCE.

THE CHICAGO ACCIDENT—ACTION OF DRY AND DAMP ATMOSPHERES ON PHOTOGRAPHY—ACTION OF HYPOSULPHITE IN THE DEVELOPER—IMPURITIES IN THE DEVELOPER—SULPHUROUS ACID AS A SUBSTITUTE FOR HYPO—INTENSIFYING WITH PERMANGANATE OF POTASSIUM—THE FALL OF PORTRAIT PHOTOGRAPHERS.

BY DR. H. VOGEL.\*

NOT without anxiety do we look forward to further news from America. The telegraph has notified us that during the Exhibition a great conflagration has devastated the city. We always follow with much interest the proceedings of the American Photographic Association, and should regret it very much if its deliberations had been disturbed by this accident; still more do we mourn that the ill-fated city has for the second time been visited by such a calamity.

We have had lately such an extraordinarily dry atmosphere, something unusual in the otherwise eternally wet atmosphere of Europe. For weeks we have had hardly a trace of rain, and this produces phenomena which affect photography injuriously, particularly with long exposure of plates and on the printing paper. Curiously enough, the Lichtdruck is also affected by it; the gelatine plate from which the print is made requires always a certain degree of moisture, and the prints which are made in the damp atmosphere of autumn are much handsomer than those made now. But aside from these matters, a dry

\* Philadelphia Photographer.

atmosphere generally is advantageous to photography. In the always damp and hot atmosphere of Aden I have met with numberless obstacles; the plates could only be cleaned with difficulty; after a few hours they attracted moisture from the atmosphere, which required an extra polishing. I could expose them for twenty minutes, thanks to the damp atmosphere, but it took an enormously long time before a plate became sufficiently dry for varnishing, and the varnish attracted moisture from the atmosphere and became cloudy. The varnish film so obtained had very little stability; after a few months it cracked, and the plates which I took at that time are now, all of them, destroyed. To take dry plates in such an atmosphere is almost impossible, simply because the dry plates would not dry. A preliminary coating with albumen was also out of place, as in a very short time small fungi would show themselves, which produced spots. Under these circumstances I prefer to work in a dry atmosphere, although here, too, we meet with plenty of difficulties.

Mr. Schaarwachter reported lately a rather curious annoyance in intensifying: the plate became suddenly dark, the shadows showed a blue-black fog, the whole picture changed and became a positive. This is generally ascribed to deficient pyrogallie acid, or a want of acidity in the developer. Neither of these causes operated here, for the intensifier did not change its action after fresh pyrogallie acid and glacial acetic acid had been added. Finally, Mr. Schaarwachter had to abandon the ordinary method of intensifying, and strengthened the plates after they had been fixed and washed. Pyrogallie acid and silver did not act injuriously. Only after a long search the cause of the above mishap was discovered: a small quantity of hypo solution had found its way into the developer. In fact, any one can produce this action by adding a small quantity of hypo to the developer. Similar results are brought about if we add sulphurous (SO<sub>2</sub>) acid to the developer. Formerly, sulphate of iron was frequently contaminated with this substance, and the consequence was that the picture became foggy over its whole surface. I remember an instance which happened ten years ago, when a photographer in Java received a supply of such sulphate from here, and who, in consequence, had to lie idle for six months, until he could receive a fresh supply. Similar faults have afterwards been unjustly ascribed to the iron, while, in fact, the acetic acid was to blame. I received from Hamburg a sample of acetic acid which, when employed as a developer, produced fog. This acetic acid was made from pyroligneous spirit. Since that time I do not use any acetic acid in the developer, but take simply two or three per cent. of alcohol, and about one cubic centimetre of sulphuric acid, to one litre of developer. The percentage of alcohol has, of course, to be increased when the bath contains much alcohol, and *vice versa*.

Although I have mentioned that sulphurous acid acts injuriously in the developer, I must not omit to mention that this body is, in other respects, of great advantage to the photographer. Until recently, the rags which are used for making paper and cardboard have been bleached with chlorine, and the last traces were removed with hypo; a small quantity of hypo remained, however, in the paper, which was apt to turn the picture yellow. The sulphite of soda is free from these disadvantages; it absorbs, likewise, the chlorine, and is, in this respect, a perfect substitute for hypo. The sulphite of soda was formerly very expensive; but the price has now been reduced so much that paper makers can use it, and we will hope that we will get rid of an unpleasant trouble with our mounts. Attempts have also been made here to bleach the mounts with permanganate of potash: this does very well; the color is destroyed, but the paper itself is coloured brown by precipitated oxide of manganese; the brown colour is removed by sulphurous acid, when the mass becomes brilliantly white.

I have lately tried again to use permanganate for intensifying. When we coat a fixed and washed negative plate with permanganate of potash, the plate becomes of a yellow-brown colour; this colour is very opaque for chemical rays, and this recommends it for intensifying the negatives of drawings, &c. A diluted solution of permanganate, one to two hundred, is employed at first; afterwards we take a concentrated one, of the strength one to one hundred. The permanganate is decidedly preferable to chloride of mercury, iodide, and sulphide of potassium, for the latter has a very unpleasant smell. Iodine and bichloride of mercury give pictures of uncertain keeping qualities, and sometimes the intensification is lost—*i. e.*, instead of the dark compounds, light chloride and iodide of silver are formed. Permanganate has none of these drawbacks.

A few days ago I read in the *Photographischen Notizen* a letter of a portrait photographer, which I consider worthy of recital.

"We portrait photographers are miserable beings, said an old colleague to me, while talking about the joys and sorrows of our business. The joys are few; I believe the only one is the pleasure of earning money. I feel like laughing when I read a description of the pleasure of having made a satisfactory picture—a picture which is the delight of the whole family, and the photographer is overwhelmed with applause. I am not vain; the least am I vain of my pictures. How often does it happen that I devote all my care, my attention, my knowledge and understanding of art to the production of a perfect picture. An elegant young damsel is posed, lighted *à la Rembrandt*, and my first operator and myself do not rest until a perfect negative has been obtained. We are both delighted, we are proud of our work, the print turns out magnificent; but what is the result? The beauty throws the picture at my feet. She had been the night before to a ball, was tired, and poor me did not know that. I could not tell whether that was her ordinary expression, or whether her beauty was still more radiant when she had not been to a ball the previous night. This has happened to me often. Sometimes I can find out the reasons why my pictures do not please; at others, not. Then it turns out that he or she had a toothache, or quarrelled with his better half, or lost a lawsuit. Again, others had to wait too long, and became angry. And in the face of such discord, the noble art of photography creates pictures, but not expressions.

"On the other hand, I know instances where the pictures were absolute failures. There was an unruly model, which could not be posed or could not sit steady; or the light was bad; or the devil played havoc with the bath or the chemicals; in short, the pictures were shameful. When I showed these abortions to my customers, and wanted them to sit a second time, what was the result? The customer was delighted, declared the picture the finest that was ever made, considered my objection unfounded, and it is horrible to relate, but true, such customers have recommended me all around. I should blush if I saw those pictures hanging on the walls, provided that I was still capable of blushing, but I have become indifferent to such things. Praise and blame run off from me like the rain from a duck. Every photographer has to be prepared to hear that the finest picture is found horrible, and he must not think that the public is malicious. The portrait painter is better off than we; he really becomes acquainted with his model, for he occupies himself with his sitter longer than a quarter of an hour. Unfortunately we have not the time for that, and this cannot be helped.

"A friend and colleague of mine once photographed my wife and little boy. It was a splendid picture, but the boy had his tedious hour, and looked in the picture so stupid and sleepy, while in reality he is just the reverse. If I should have paid for the picture, I would have rejected it, in spite of all its brilliancy, sharpness, light effects, &c. 'This happens to us often—we poor portrait photographers.'

## HOW TO AVOID UNNECESSARY WASTE OF TIME AND SILVER.

BY E. Z. WEBSTER.\*

DOUBTLESS the following will strike some of my brother photographers as an unnecessary waste of words; but the result of twenty-seven years' experience in the business has satisfied me that not one photographer in fifty makes a systematic and economical use of his silver and gold; and time, which is money. A properly graduated scale would place time high above all other treasures, and still it is more lavishly wasted. No ambitious photographer can afford to waste his time, and certainly no real devotee of our beautiful art ever need waste a moment. Every hour of daylight is pure gold, and should be devoted to those purposes which can only be successfully prosecuted by day, leaving until night those things which can just as well be attended to at that time. Of course I am addressing the ambitious, and the devotee. If you are an old veteran our advice is unnecessary, but those who have a name to make will please take heed.

Many things can be done by lamplight which will economize your daylight. If you are master of every branch of your business you will find enough to do; and if not master, you will find enough to do as pupil. Study, study, study; read everything pertaining to your business; think it all over; cull out a word here, an idea there, and put into practice every useful hint and available suggestion. Notwithstanding my many years of experience, I find so much which is new to me, and so much that is useful, that I can but wonder how any photographer can possibly succeed who neglects his printed opportunities. Of course, there is great diversity of opinion in regard to the various processes: one writer advocates one plan or formula, and another writer condemns that, and recommends another which is diametrically opposed; and still each seems to produce successful results in the hands of those who can work it; but no one can succeed who tries to follow all the paths. He must take some one which he has confidence in, and follow it up and make that his general plan, and then work, study, think, and press into service every available hint, suggestion, and idea which can be obtained.

The waste of time and opportunities is more important than all other waste put together, and any one who does not economize in all things, does not economize at all. And here let me explain by saying that true economy sometimes seems an absolute waste; but the final result must always be considered, and if the object gained is worth all the labour, time, and treasure which has been expended, well and good; but if the same object might have been attained at a less cost of time and treasure by a more judicious expenditure of either, then there was a lack of economy. Many photographers are deluded with the idea that a "silver-saving apparatus" would insure their everlasting salvation pecuniarily, and because they are told that nearly all the silver used in their business can be recovered, the utmost carelessness is practised, consequently from fifteen to thirty per cent. more silver is wasted than is necessary, and the unnecessary waste is greater than the clear saving of any "silver-saving process" in use. Of course, no one can deny the propriety of saving all the silver which can be saved economically, but it requires more judgment to determine when, where, and how to save silver, than it does to run a steamboat, because the relative value of time and silver is constantly and sometimes momentarily transposed, and when a man gets silver saving on the brain, he will follow up and corner the last drop, and ferret out and bag the smallest scrape, even though he may have a sitter in the chair and a dozen more waiting.

Suppose you could save seventy-five per cent. of the silver used, if you will count the cost of time and trouble expended in saving so high a percentage, and then deduct the unnecessary waste which you made thinking it could

\* Philadelphia Photographer.

"most all be recovered," then deduct that twenty-five per cent. for refining, allowing the refiner to do the figuring, and when you get through you will find the silver you have saved has cost you about one hundred dollars per pound.

Further, I claim that the term "waste or spent solutions" is a misnomer, and does not apply to any solution containing any substance which we wish to retain or reconvert to the same or any other purpose. When the silver has been precipitated from hypo, cyanide, or any other solution, the remaining solution may be "waste or spent," provided we have no other use for it.

The same remark holds good in regard to the chlorides, sulphurets, &c. When the silver has been extracted therefrom the residues or refuse constitute waste, and nothing else.

Finally, I claim that the most economical way to save silver is not to waste it unnecessarily, and in our next paper I shall point out some of the holes through which silver escapes, and will endeavour to suggest a partial remedy.

(To be continued.)

## Notes and Queries.

### FUMING SENSITIVE PAPER.

SIR,—It has been more than once suggested that the subject of fuming sensitized paper should be discussed in your new column of "Notes and Queries," but no one has volunteered to open the question. The American writer on Practical Printing takes the practice of fuming for granted, and only seems to think it necessary to discuss the best manner. Will any of your readers who may have had experience in fuming be good enough to enlighten the fraternity as to its advantages or disadvantages? Is not the fuming of the pad to be placed at the back of the paper as good as fuming the sheets?

THETA.

SIR,—The suggestion made by "Senex" on the 14th ult., as regards fuming, is a very good one; as I think it would be of great service to some photographers in England to understand a little more about fuming. And what better plan is there of finding advantages and disadvantages of fuming than by a few good practical men taking up the subject, and giving their experience, whether it be successful or unsuccessful, fully describing the chemical action caused by fuming, and the adding of salt or acetic acid to one of the washing waters, so as to redden the prints previous to toning, and whether it is best to have the toning bath slightly acid, neutral, or alkaline? If the subject is taken up, I will give you my experience with the fuming box in America. Enclosed, I send a few photographs taken in the vicinity of Boston, which I hope our dear Editor will criticise, as the paper was fumed from fifteen to thirty-six minutes. I may mention, for those who want to experiment on fuming, that they should get a box that will not let the fumes escape, pin a sheet or two inside, then get a saucer and put about an ounce of the strongest liq. ammonia, turn the box bottom-side up, with the ammonia underneath, and let her go for from ten to twenty-five minutes, according to the brand of paper they are using, &c. Do not be afraid to fume long enough, and see that your paper is thoroughly dry before putting it in, or else it is certain failure. Hoping to hear more anon on fuming, I remain, yours respectfully,

AMERICAN.

### DRYING SENSITIVE PAPER.

SIR,—The "Practical Printer in America" refers to the necessity of drying the paper after sensitizing. Is this necessary, and which is the best mode of going about it? I have always been in the habit of allowing mine to dry spontaneously. Will any experienced printer say if any important advantage is gained by drying by artificial heat?

AN APPRENTICE.

### MOUNTING WITHOUT COCKLING.

DEAR SIR,—Can you tell me of any plan by which I can mount large prints on thin cardboard without its cockling? Some time since I had to mount some 10 by 8 on paper to be bound in a book, but could not get them flat. I tried straining the paper on a drawing board; when dry, mounted the pictures; then let

remain till thoroughly dry, when it looked very well till I let the edges loose, when it at once began to curl. The only way I could get anything respectable to please me was by printing on a large piece of thick salted paper, covering the negative, &c., with a piece of black paper cut out to form margin. Now, is there no known way to mount a print as flat, or how do they make thin cardboard so flat? I have tried damping the cardboard, but it was not successful, and nearly spoilt the cardboard.

I use starch for mounting. I find, of course, the quicker I can get the pictures to the card the better after it is damp, but they will not lay flat if not thoroughly pasted.

Now, an answer to this query would, I think, be extremely useful for I find, by pictures I see, that others are in the same state as myself. And I think we ought to be able to mount (say) a photograph on albumenized paper 17 by 12 on eight-sheet cardboard, and get it as flat as the cardboard was before, for a thicker card seems so clumsy and unnecessary in a portfolio, though it would not matter how thick it was in a frame.—I remain, yours respectfully,

R. HOULSON.

If you consider any material more suitable than starch, would you be so kind as to explain?

### PHOTO-MECHANICAL PRINTING.

SIR,—From time to time you are so good as to inform your readers of the progress of photo-mechanical processes on the Continent, and to encourage its development in this country through your widely-spread journal. Captain Waterhouse has given us occasionally details of his mode of working, and I shall be greatly obliged to any of your readers who have tried his method with success for any hints on the subject: specifying the kind of gelatine used and where to obtain it, the mode of drying, and any hints upon substratum, what kind of rollers to use, and where to obtain them.

Trusting you will give insertion to this enquiry in your Notes and Queries column,—Yours obediently,

GRENATINE.

## Correspondence.

### EXHIBITION OF THE PHOTOGRAPHIC SOCIETY.

SIR,—I have the honour to inform you that the forthcoming exhibition of the Photographic Society of Great Britain, which will include the works intended to compete for Mr. Crawshaw's prizes in portraiture and landscape, will be opened with a *conversazione* of the members and their friends at the Suffolk Street Gallery, Pall Mall, on Tuesday evening, 13th October, at seven o'clock.

The exhibition will remain open until the 5th November (Thursday), from 9 a.m. till dusk daily; also on the evenings of Monday and Saturday, as well as the last day, from 7 till 10 p.m. Admission will be granted by tickets issued by the members. A fee of one shilling will be charged to all who are not provided with members' tickets: evenings, sixpence; both to include the catalogue.

In order to afford time for properly classifying and hanging the pictures and preparing a detailed catalogue, it is requested that intending exhibitors will send in their works not later than the 7th October (carriage paid), accompanied by a letter of advice addressed to the Secretary at the Gallery. This letter should contain the title and description of the pictures, and such other particulars of processes, &c., as may with advantage appear in the catalogue. The prices also may be stated if the pictures are for sale.

As a matter of convenience, each frame should have the artist's name and subject written on the front; and, in the event of its being intended for the Crawshaw competition, that fact should also be announced.—I am, yours, &c.,

R. J. FRISWELL, F.C.S., Hon. Sec.

### THE DOUBLE PRINTING PROCESS.

SIR,—The following method of combination printing I have found to be quick and good:—Take the sitter against a white background, finish the negative in ordinary way without varnishing, dry well, and then paint with camel hair pencil over the figure with mixture of gelatine in saturated

solution of gallic acid; when well dry, immerse in bath of iodine in iodide of potassium until all the silver around the figure is changed into iodide of silver; wash and dip in negative bath, then expose under transparent positive; finish in ordinary way.

F. J. D.

#### PICTORIAL BACKGROUNDS ADDED TO NEGATIVES.

MY DEAR SIR,—In your append to my letter in this day's PHOTOGRAPHIC NEWS, you say that the process "has produced a harsher, coarser result." Is this not a mistake? If not, it is in opposition to your former statement. Perhaps the background print I sent you was overtoned; but harshness or coarseness is no inherent part of the process I recommend, as you will see by the enclosed print, which is from an old varnished negative treated with the graphite process without removing the varnish.

Since the first announcement of my method of producing pictorial backgrounds at pleasure, or after the sitting, I find that I can manipulate old varnished negatives as well as unvarnished films. In fact, it is a matter of indifference to me whether I re-sensitize the film immediately after washing, after drying, or years after varnishing; but I think the best results are obtained by re-sensitizing immediately after washing off the fixing solution. If the latter be resorted to, the bichromate must be washed out. This is easily done by allowing the whole of the surface to harden in the light, after developing the background with graphite, and then placing the negative in water until the bichromate is dissolved. Dry and varnish afterwards, and the negative is in its normal condition as regards intensity, light and shade, &c., only with the background added.—I remain, dear sir, yours truly,

J. WERGE.

11a, Berners Street, Oxford Street, Sept. 4th.

[The print accompanying this letter is soft and delicate, and quite free from harshness. We are not aware of any opposition in any of our respective statements on the subject.—Ed.]

#### THE STATUS OF PHOTOGRAPHY.

SIR,—I cannot allow the letter of "A Photographer" to pass unanswered, as it seems to me to cast an unnecessary and undesired slur upon a class of hard-working, conscientious men, who do the very best they can according to their light and ability.

I have for a long time had a violent attack of *cacoethes scribendi*, occasioned by the never-ceasing cries of those who are evidently opposed to free-trade, and would like to keep the practice of photography within their own narrow circle. They draw their line, I suppose, somewhere (but I notice it is usually a matter of *price*, not *quality*); but whether the line of superiority be 8s., 10s., 12s., 15s., or 21s. per dozen, I cannot fathom.

"A Photographer" thinks that low prices have caused the public to under-estimate photography. I think, on the contrary, that it is the execrable work turned out by a parcel of low, semi-educated men, of hybrid profession—half tobacconist, sweetstuff dealer, or fancy shopkeeper, and the other half supposedly photographer. It is not the price, for I know plenty of photographers who charge 10s. a dozen for cartes, whose work would disgrace a back slum; and, on the other hand, there are many who send out cartes at 5s. and 6s. per dozen, which would compare favorably with the best produced.

I know not in what way photography differs so essentially from ordinary business, and I do not clearly see why the well-known laws of supply and demand should not be applicable to it. The public of the middle and lower classes cannot afford to pay the higher prices, and as we can afford to produce a most excellent retouched portrait at the lower prices, why, in the name of common sense, should we not do it?

Surely, sir, in these enlightened days, it is an excess of

absurdity to talk about keeping up the prices in order to secure the *status* of photography, and to sneer (as very many do) at those who, finding the aristocratic market fully supplied, seek a livelihood elsewhere.

Many, like myself, have seen the wretched work given to the public at low prices; but nevertheless the public have accepted it *faute de mieux*. Some of us have resolved to give first-rate work at 5s. or 6s. a dozen, and to raise the status by producing artistic and well-finished work only. We have done it; the public appreciate our efforts, and crowd to us; it pays us well, and satisfies them. Now, I ask, are we raising or depressing the status? Let common fairness decide.

I am well aware that it would be unpleasant for a man to start a studio close to mine, and offer excellent cartes at 2s. 6d. per dozen; but I should simply bide my time. The matter would find its level. If I found the new man really could produce first-rate work at his quoted price, I should look around, and ascertain the "how" and the "why." I might conclude that it was time for me, in an advancing age, also to be up to the times, and try to meet a public want. If he turned out bad work, I should leave him to the public; I do not see that I should derive any benefit by taking any notice.

There are doctors who charge 5s., and those who charge 21s. per visit; but I am not aware that the status of the medical profession is lowered because the former offer the best advice for a moderate fee, and meet an urgent public want. The root of the matter is here. "A Photographer," and hundreds like him, are afraid that the same quality of work now done at 10s. will be done for 5s. Let me tell him that it undoubtedly will. It is useless to try the Partingtonian scheme of protecting the high prices. I assure him there are many as well qualified and educated as himself, who intend to produce the best they know how at the lowest remunerative price, just as in any other trade or profession. To my mind all the "high falutin" talk about "profession," and "status," and "atelier," and "client," smacks of the *parvenu*, trying to hoist himself into a position to which he has no claim whatever.

By all means let us associate together and help each other in every possible way; let us do our best, by imparting technical knowledge, to raise the *quality* of work, and the proficiency of operators, so that the inferior, careless, and disreputable may be driven to the wall; but pray, sir, do let us cease to talk such utter nonsense about "prices" as seems just now the fashion.—I remain, sir, yours truly,

PALMAM QUI MERUIT, FERAT.

#### Talk in the Studio.

CORNWALL POLYTECHNIC EXHIBITION.—One or two omissions occurred in our correspondent's report of the awards at the exhibition. He says:—"A second silver medal was awarded at the recent exhibition of the Royal Cornwall Polytechnic Society to Mr. E. Smith's "Warwickshire Lane." Mr. Smith's exhibits included a composition entitled "The Gleaner." The background shows a series of fields of uncut standing wheat, scarcely in keeping with the idea of gleanings, which generally follows the cutting of the corn. Messrs. Hudson and Purnell's picture is named "Crab and Lobster Hotel, Ventnor;" and Mr. Bennett Lowe's portrait, enlarged and printed in carbon, did not arrive in sufficient time to pass under the eyes of the judges. I must apologise that, in the hurry of writing to save mail for that week's publication, these notes should have been omitted."

DARK MOUNTS FOR CARD PORTRAITS.—We have already called attention to the effective mounting which has recently been adopted by some portraitists for cards. We have just received some examples from Mr. A. W. Wilson, of Kingsland, which are exceedingly charming. They consist of Rembrandt heads admirably posed and lighted, the bold and effective masses of light and shade being combined with perfect delicacy and fine modelling. The rich effect is much enhanced by the chocolate tint of the mounts, closely assimilated to the tone of

the prints. The retouching is effected with much skill and taste, and is, we are informed, the work of Mr. Carl Becker, of Dresden. For "Rembrandts" we especially commend the chocolate mount.

**REMBRANDT PORTRAITS.**—A writer in the *Brighton & Wily Mail*, noticing in very high terms Mr. Boucher's portraits, says:—"As it is really a novel feature in photographic art, I was rather pleased with the Rembrandtesque portraits. The title given to these peculiar pictures is not a misnomer. Rembrandt's style consisted in throwing all the faces which he painted into strong relief by an intensely dark background, which extended its shadowy influence to a part of the countenance itself. This style has been most felicitously imitated by the Brighton artist, and is worthy of encouragement on all hands."

**THE ORIGIN OF THE TRIPOD STAND.**—Mr. E. L. Wilson, in some interesting sketches of his rambles whilst in Europe, details his visit to Vesuvius, after which he had a dream which clears up all mystery that may be connected with the origin of the photographic tripod, and ran thus: "The Devil, who had heard that Vesuvius not only rivalled him in the overpowering influence of its sulphurous fumes, but also that the crater was ten times more to be feared than his most heated chamber, one day at dusk paid it a visit. He walked proudly up to the crater, tail in air, to the very verge, when, beholding its awful depths, he lained, dropped his tail to the earth, fell back upon it for support, and thus supplied the missing idea for the third leg of the tripod."

**CRACKING OF VARNISHED FILMS.**—A correspondent of Anthony's *Bulletin* mentions a recent experience relative to cracking films. He says:—"The negatives which remain good were evenly warmed (not made hot, a mistake too often made) before flowing the varnish, which was allowed to remain on the plate sufficiently long to permeate the film; after draining, held over the fire, taking care not to make the plate too hot until the varnish had set. After getting cold, they were set in the sun until they became quite hot; they were then taken in, and allowed to harden up, when they are prepared to stand any amount of hard work."

**ALL THE SUN'S RAYS ACTINIC.**—The power of chemical decomposition does not particularly belong to the violet end of the spectrum, but is found throughout its whole length. But bromide and iodide of silver, as used in collodion photography, are more readily decomposed by vibrations of certain lengths and periods than by others, and hence the excess of action seen at the violet end is a function of certain silver compounds, and not of the spectrum. Other substances, as carbonic acid, show maxima elsewhere, as in the yellow region. The solar beam is, therefore, not compounded of three forces—light, heat, and actinism—but it is a series of ethereal vibrations, which give rise to one or other of these manifestations of force, depending on the surface upon which it falls.—*Draper.*

## To Correspondents.

**AMERICAN.**—Your specimens are very good indeed for a youth of nineteen years, being, indeed, over, rather than under, the average run of portraiture supplied to the public. Printing and toning are excellent, the lighting good, posing generally good, but might, in one or two instances, be improved. The retouching is well done, but, in some cases, almost in excess, giving too much smoothness; but it is just what the public for the most part like.

**R. BLUNDELL.**—The toning bath with tungsate of soda gives very good results, but we have no reason to think that it is easier to work than the acetate bath, which is found, as a rule, to be one of the simplest and safest. You will certainly not get it to work well after it is dark coloured, nor, indeed, any other gold toning bath, as the dark colour marks decomposition. This dark colour may be due to various causes. If the toning bath is kept in the light, it is apt to precipitate the gold, and the solution will assume a purple tint. If the solution has been touched with soiled fingers—especially fingers which have touched hypo—it turns brown; but in all cases after the toning bath is discoloured there is an end of its usefulness; it may be thrown into the residues. Much depends upon the class of pictures, and the depth of tone, and the mode of working, as to how much paper a grain of gold will tone. Some think one sheet sufficient, some two, and some secure more. A sheet of vignettes would require much more gold than a sheet of fully printed-out Rembrandts. A trace of silver left in the paper before toning often aids toning. It has not much to do with the permanency of the picture, as all silver is of course removed in the hypo. The prints should be washed after toning, in order to avoid risk of decomposition of the hypo by any trace of acid in the print.

**M. L. F.**—You will see, from a letter in another column, that the Exhibition will be held next month. It was definitely resolved not to give medals this time.

**FERROTYPIST.**—Most of the conditions of obtaining a good collodion positive on glass are equally applicable to the production of a good ferrotype. In some cases it will happen, however, that the image which gave a good result on glass is not quite suitable for a ferrotype, and the dullness of which you complain in yours, as compared with what you used to obtain on glass, is very likely to arise from one of the causes to which we refer. When a thin collodion, yielding a thin, delicate image, is used for positive work on glass, if the image be of good colour, it will yield a fine picture if backed with velvet; if the back of the glass be black varnished, it will be a somewhat duller grey picture; and if the black varnish be applied to the collodion side, a very dull grey picture would result. The last position is very similar to that in the ferrotype plate: the image is in immediate contact with the black surface, and the thin image is not sufficiently opaque in the whites to give any brilliancy, but looks grey all over. You will see, then, that with the ferrotype plates it is necessary to use a collodion of good body, and one yielding a brilliant image. A good developer consists of fifteen grains of iron, fifteen minims of acetic acid, two minims of nitric acid, and one ounce of water. It is better a very few days' old, and we prefer to filter that which has been used back into the stock bottle. The trace of silver it holds in solution aids in securing a brilliant white image. Cyanide which has been used gives a whiter image than a fresh solution.

**R. HOULSON.**—We give your question place in the "Notes and Queries." We should, however, recommend glue in place of starch.

**HALCYON.**—The two lenses you require are only made by one maker, the one you name. You would not obtain them in any case of lenses, nor, indeed, of any French maker at all. You will find it wise to obtain them of the maker. 2. It is possible; but we cannot say with certainty. 3. Good; but not, we think, equal to those of the English maker.

**MELBOURNE.**—The best kind of crucibles for melting down residues are known as "London pots"; we do not remember the address where they can be purchased, but your London stock-dealer will doubtless obtain them for you. Occasionally they crack with the heat, and it is a good plan to make safe by using one within another. Plumbago crucibles are less liable to crack; but when the temperature is high they are sometimes attacked by the heat and flux, and so melt. 2. The proportions of flux you name are about right. 3. A printer has no right to print more copies from a negative than you order; and if he dispose of any copies so printed, he is guilty of dishonesty, which the law will punish. If a printer has printed more copies from your negative than you require, you cannot demand them without payment; but you can demand that they shall be destroyed; but we think that no printer would be so unwise as to act in such a dishonourable and dishonest fashion as you mention.

**S. W. O.**—The object of partially unscrewing the back lens in the patent lenses is to get depth of focus without loss of light. When you place a stop in a lens to gain depth of focus, you lessen the light and increase the exposure, which is avoided by unscrewing. The position of a sitting figure naturally favours the curvature of the lens, and hence it is not difficult, with most reasonably good lenses, to get the necessary parts of a sitting figure in focus. For standing figures you must use a lens of longer focus, or use a smaller aperture, or use a lens with specially flat field, in order to get good results. With the lens you use for cabinets you must use a small stop to get standing figures in satisfactory focus. A lens of the same diameter, but shorter focus, will be more rapid, but will not cover so well.

**ANATEUR.**—Your negative has not reached us.

**B. L. M.**—Your negative arrived in useless fragments. Placing a plate of glass between pieces of cardboard is worse than useless: worse, because it troubles us with innumerable dangerous splinters of glass, and nothing we can examine. A box should always be used. We append for your benefit and that of many others some hints sent us some time ago by Mr. G. Tully as to the best mode of packing negatives for transit:—"A strong box filled quite full with bran or sawdust, the negatives being placed in centre wrapped separately in paper. Another is to tie the negatives tightly together, with a piece of blotting-paper between each negative; wrap them up firmly in a large cloth or wrapper until you make the parcel large enough to fill the box tightly (any old piece of soft material serves this purpose). Another very simple one is (say you want to send twenty negatives) to place a strong elastic band on the two ends of ten, then place the other ten alternately with these, putting a strong one round the whole, or tie them together firmly; wrap round in a sheet of cotton-wool, place them in a strong box, filling in the space with waste paper, or anything to keep them from shaking. I know these to be good and safe plans, never having found them fail."

**J. H. FREITASSEN.**—We do not know the address of the gentleman to whom your note was addressed. He does not reside in England. Our pages have, however, contained full details.

## The Photographic News, September 18, 1874.

## PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHIC STATISTICS.—THE ILLUSTRATION COMPANY—  
THE SAHARA DESERT PHOTOGRAPHED.

*Photographic Statistics.*—Here is some information about photographic societies and photographic literature for those who like statistics. There are at present twenty periodicals in the world devoted exclusively to photography, besides six annuals. Of the latter, two are published in this country, our own having been the prototype of all the others; two in America, *Photographic Mosaics*, and *Photographers' Friend Almanac*; one in France, *Annuel Photographique, par Davanne*; and one in Austria, *Photographisches Jahrbuch*. Of the twenty periodicals that appear weekly, fortnightly, or monthly, there are at present three in England; two in India, *The Journal of the Bengal Photographic Society*, and *Indian Journal of Photography*; and as many as five in America, viz., *Philadelphia Photographer*, *Humphrey's Journal*, *Photographic World*, *Anthony's Photographic Bulletin*, and *Photographers' Friend*. There are three journals published in the French language, two in France and one in Belgium, the *Bulletin de la Societe Francaise de Photographie*, the *Moniteur de la Photographie*, and the *Bulletin Belge*. A few months ago there were seven periodicals published in the German language, but of these, two (the *Heilos*, of Dresden, and *Licht*, of Berlin) have recently ceased to appear; of the five journals now appearing, two are published in Vienna, the *Photographische Correspondenz* and *Photographische Notizen*, one at Elberfeld, the *Photographisches Archiv*, and two at Berlin, the *Photographische Mittheilungen* and *Photographische Zeitung*, although the latter, we believe, has not appeared lately. There is one journal in the Dutch language, *De Navorscher op de Gebied der Photographie*, and one published in Italy, at Brindisi, entitled *Rivista Fotografica Universale*. As regards photographic societies, they are more numerous even than the periodicals, there being no less than twenty-eight societies now in existence for aiding progress in the art. Of these there are eleven in America, eight in Great Britain, four in Germany, including the Hamburg and Dresden societies, two in France, that of Paris and Marseilles, one in Austria, one in Holland, and one in Bengal. It is difficult to get an accurate statement of the number of members in these societies, but in the principal societies of London, Paris, Berlin, and Vienna, the members may be thus roughly put down:—The London Society at the last anniversary numbered 300 members; the Vienna Society has 280 members; the Society for the Advancement of Photography at Berlin has 220, and the sister society in the same capital, 240; the Paris Society has about 200 members; that of Dresden, 90, and that of Hamburg, 30.

*The Illustration Company.*—It is to be hoped that the new Illustration Company which has just been started, with so practical and experienced a director as Mr. Henry Blackburn, will afford a market for photographic work, and thus supply some incentive for photographers to make pictures such as might be suitable for illustrating letterpress. As a well-known author and artist, and also editor, Mr. Blackburn seems eminently qualified to act as a mediator between photographers and publishers, and there is every prospect of the former receiving fair payment for their work, instead of, as has been frequently the case of late, their works being copied, wholly or in part, without recognition. Photographers may now set to work to make *genre* and other pictures with good hope of reward, for hitherto the time and labour expended in the conception and carrying out of works of this kind were almost thrown away, for one could look for no return unless the picture happened to be noticed by the public, and a few score of copies were sold. For this reason but

few of our high class photographers occupied themselves with the production of these studies, for beyond a little honour and glory there was little else to be gained. The Illustration Company seeks to become a mediator between photographers and the public; and as the profits of the company is to be a percentage upon the sums paid over to photographers, it will be to its interest as well as to that of photographers that as many pictures are published as possible. The new concern is one more recognition of the art qualities and value of pictorial photographs, and we cannot but think that its establishment will be highly beneficial to the photographer in protecting his interests and finding a market for his commodities.

*The Sahara Desert Photographed.*—M. M. Remelé, who is accompanying Gerhard Rohlff's North African expedition as photographer, has been exceedingly successful in his work, and promises to bring back records of his journey such as have never yet been afforded us by African travellers. There is always a little disbelief attaching to the account of African travellers, and sometimes, as in the case of Du Chaillu, people at home refuse to listen altogether to the traveller's narrative. With M. Remelé's aid, it will be possible to bring back proofs secured by means of the camera which cannot be gainsaid; and if only such pictures can be reproduced and printed by a mechanical process, and employed as illustrations to a book, their value will be increased a hundredfold. The stock of glass plates and chemicals with the expedition appears to be exhaustless, and of the Sahara desert alone a series of sixty good pictures have been secured. This series forms one volume, or album, by itself, and the Viceroy of Egypt has expressed himself much pleased with the work; his opinion being, indeed, so favourable that he has requested that sixty albums be at once produced for himself alone. We are glad to hear, moreover, that M. Remelé contemplates the writing of a photographic report of the whole journey, which, besides being an interesting volume, will doubtless be of incalculable value to the travelling photographer in hot climates. The Berlin Society for the Advancement of Photography has the honour to number M. Remelé among its numbers, and it is to that body, therefore, that we must look for an account of his experiences in Africa. Some of the pictures have already reached Berlin, and are to be submitted to the society at an early date.

ON THE PHOTOGRAPHIC TRANSPARENCY OF  
VARIOUS BODIES, AND ON THE PHOTO-  
GRAPHIC EFFECTS OF METALLIC AND OTHER  
SPECTRA OBTAINED BY MEANS OF THE  
ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

## I.—ABSORPTION OF THE CHEMICAL RAYS.

a. *By Transmission through Solids.*

6. The general arrangement of the apparatus employed in this inquiry is represented in fig. 1, in which the observer is supposed to be looking down upon the instrument: *cc* is a camera which allows of a considerable range of adjustment, and is attached to a cylindrical box, within which is a prism *b* of rock crystal. At *l* is a quartz lens of  $1\frac{1}{2}$ -inch aperture and  $17\frac{1}{2}$  inches focal length. At one end of the tube *t*, which can be lengthened or shortened by a sliding joint, is a slit *s*, provided with a screw for regulating the width of the opening. This slit is arranged parallel to the axis of the prism, and in these experiments was adjusted to a distance of 37 inches from the lens *l*. The prism is placed at about its angle of minimum deviation for the mean ray, and, for facility of manipulation, can be turned round upon its own axis by means of the lever *a*. The angle formed between the camera and the tube *t* also admits of variation as circumstances may

require. At *d* is placed the substance the transparency or which is to be tested; and at *e* are the metallic electrodes, which are connected with secondary wires *f, f* of a 10-inch induction coil, not shown in the figure. The wires of the coil terminate in electrodes composed of fine silver. The coil

was excited by means of a battery consisting of five elements of Grove's construction, a condenser being included in the primary circuit, whilst a small Leyden jar, exposing about 75 square inches of metallic coating upon each of its surfaces, was introduced into the secondary circuit. In this way a torrent of sparks could be maintained between the electrodes at *e*, without any sensible variation of power, for ten minutes at a time, or longer if necessary. In these experiments an exposure of the sensitive plate for five minutes in the camera was requisite.

At a suitable distance behind the lens (about 26 inches\*), a collodion plate coated with iodide, or occasionally with a mixture of iodide and bromide of silver, was supported in the camera, for the purpose of receiving the image of the spectrum.† The plate was excited by the use of a bath of nitrate of silver containing 30 grains of the nitrate to an ounce of water. The image was developed in the usual way by means of pyrogallic acid, in the proportion of one grain to the ounce of water, and fixed with cyanide of potassium.

7. The spectra of electric sparks so obtained were remarkable for their great length; indeed they extended beyond the termination of the visible rays for a space equal to five or six times the length of the luminous portion.

For the convenience of comparing the results of the various experiments together, I have adopted an arbitrary fixed scale, the fiducial point of which is the line H in the solar spectrum. Calling this 100, the more refrangible rays are numbered onwards, and the less refrangible rays backwards

\* This distance was found by experiment to give nearly a flat field, with the image of the slit formed by all the different rays in focus simultaneously. My friend and colleague, Professor J. C. Maxwell, kindly calculated for me the relative positions of lens and prism necessary to ensure an approximately flat field for the visible rays. If the lens be placed between the slit and the prism, a very great difference occurs between the points of convergence of the most refrangible and the least refrangible rays, amounting, with the lens and prism which I used, to nearly fourteen inches. When the lens is before the prism, both coincide in augmenting the convergence of the more refrangible rays; whereas, when the lens is placed behind the prism, the convergence occasioned by the lens is neutralized by the prism, which now acts in the opposite direction upon the diverging rays as they fall upon it from the slit.

† My friend Mr. Pizoy, who assisted me in these experiments, prepared the collodion for me, following nearly the directions given by Hardwich in his "Manual of Photographic Chemistry," sixth edition, page 262. It was iodized with a mixture of equal parts of iodides of potassium and cadmium, and was perfectly uniform in its action, even for weeks after it had been iodized, if kept in the dark.

from it, the line B in the solar spectrum being at 84; the length of the spectrum from silver points extends from 96.5 upon this scale to 170.5. The solar spectrum for the purpose of this comparison was projected upon the collodion plate by means of a small mirror of polished steel (*g*, fig. 3) placed so as to form an angle of 45° with the surface of the plate carrying the slit, and to cover a portion of the vertical slit, as shown by an end view of the tube at *g*, fig. 2, whilst the direct image from the silver points fell simultaneously, parallel to that of the solar spectrum, upon the collodion plate in the camera.

(To be continued.)

## HOW TO AVOID UNNECESSARY WASTE OF TIME AND SILVER.

BY E. Z. WEBSTER.\*

In my first paper I endeavoured to impress upon the minds of my brother photographers the value and importance of saving time.

We will now proceed to the next and main subject under consideration, *i.e.*, the unnecessary waste of silver, and how to avoid it; and as the making of the negative is the first use, there is the proper place to commence the saving of silver.

Although I do not propose to teach the art, or to criticise the pet formula or processes of my brother photographers, still I must give my own views upon all points bearing upon the subject under consideration; and while I would not arrogate to myself one tithe of the knowledge possessed by the many great and brilliant exponents of our beautiful art, still I believe there are scores of operators who have not yet "learned everything," and some things which I have learned may be of use to them.

One thing I have learned is this, *viz.* it don't pay to be everlastingly at war with our negative bath; and any man who tries to make his bath work all sorts of collodion, all sorts of developers, acids, alkalies, dirty plates, and everything else, will always be in a chronic state of perspiration and uncertainty, not to mention the immense amount of silver and other materials wasted.

A good forty-grain bath is the most reliable and best adapted to the various commercial collodions in the market; and, unless you are an adept, I would not advise you to confine yourself to "home-made" collodion.

See that every plate is absolutely clean upon the back and edges, and chemically pure upon the front, and free from dust when it goes into the bath, for dirty plates are an abomination—they spoil the picture, sour the temper, soil the bath, and disgust the sitter. Try to reduce your negative process down to the utmost certainty by careful attention to every detail of preparation, and then watch every shade of chemical change, thereby enabling you to nip disaster in the bud. The making of the negative is the most critical and the most important part in the photographic process. Volumes have been written upon the subject, and yet there is no one accepted rule or standard formula; but I will take it for granted that you know all about it.

Every operator knows that the negative solution must be free from all floating particles, as well as from chemical impurities. There are various means of remedying the latter, while the former must generally be filtered out; consequently, some operators are always filtering their bath, and the unnecessary waste of silver by so doing is surprising; the filters absorb large quantities of silver, to say nothing of the slops which seem almost unavoidable.

I weighed a new nine-inch filtering-paper, and then filtered the bath solution which I had been using, containing about one gallon. The filter before using weighed about 100 grains; the same filter, weighed when wet, and had stopped dripping, 306 grains, and, when thoroughly

\* Continued from page 44

dry again, it weighed 180 grains; another filter just like it which was used immediately after, weighed 150 grains when dry: while some old filters, which have come under my observation, were very much heavier. Of course, the larger the filter, the more solution is absorbed. The use of cotton may be more economical, still there will be great loss. And then, again, it is not always convenient to stop to filter. Now, if you will take a box of suitable size, minus a top, and set your bath into it (see fig. 1), and, just as soon as your

plate is dipped, tip it (the bath) forward (see fig. 2), and let it remain in that position until you are ready to remove it to the plate-holder, you will be astonished to see how free from pinholes your negative will be, and it will save you an immense amount of filtering. I have been practising this plan for many years, and am surprised that so few operators have adopted it. This box may be filled with warm water in cold, and with ice-water in hot weather, thereby securing a more uniform temperature of the solution. Much solution is allowed to drip upon the floor, and elsewhere, by unnecessary haste or carelessness in removing the plate from the bath. Of course there are times, and very often, when it is necessary "to push things," and then "quick" is the word, "hurry up the plate." Do not stop for the drip, but, if you are working large plates, it will pay you to fix up an arrangement like the one represented in fig. 3, which should be fastened to the wall of the dark-room at the proper height, and as close to your bath as possible, so as to avoid the waste of solution while passing the plate to position. While the plate is draining, you can get your plate-holder all in readiness, or coat and dip another plate. &c., and the silver which is saved is all ready to use again. It does not require refining, and is not subject to a royalty grab, nor does the silver which can be saved by following the suggestions contained in this series of papers. The main object to be kept in mind must be to retain the silver in the original, or some other workable form, by the simplest and most economical plan; and I will guarantee that the amount of silver which can be saved by a systematic routine of avoiding unnecessary waste will be twice as great, and no more troublesome, than the endeavor to regain your contaminated silver by sending it to the miller, who keeps the grist and sends you the toll.

(To be continued.)

THE TRANSIT OF VENUS.\*

WITHIN the next three weeks the last of the parties who are to observe the transit of Venus in December next will have left England. Its destination will be Egypt, and the

\* Daily News.

present intention is that one section of it should remain at Cairo, whilst another proceeds to Thebes, some 400 miles further up the Nile. At this latter place a private English expedition under Colonel Campbell will also be located, as will one from Russia under Dr. Döllen. Our official detachment at Thebes will be almost exclusively devoted to photographic observation. The original idea was that the whole of the staff should remain at the capital; but recent experiment has shown that the low altitude of the sun (viz., 15° at the most important time of the phenomenon) was unfavourable for securing the highest results with photography. By moving to the south-east 20° will be obtained, and the certainty of a good record ensured.

Egypt as a station will be exceptionally circumstanced. At all the others longitude will have to be found by the slow and laborious process of human observations, whilst there it will be determined by telegraph direct from England. The importance of fixing the meridian of Cairo or Alexandria by this most accurate method can scarcely be overrated. Either of these places will be a most suitable point whence all countries to the east, if connected by cable with them, will be able to fix their relative positions with respect to Greenwich. For navigators, the ascertaining of the true longitude of distant ports is of vital interest, especially in regard to the rating of chronometers. Of the four expeditions which have already sailed there has been but little intelligence. We trust, however, that no one of them has suffered the loss that has occurred to that organized by the Indian Government, namely, of a valuable assortment of photographic chemicals, which were thrown overboard on the passage out from England. In this instance the damage is not irreparable; but in the case of any of the others it would be very serious. As ill news travels apace, we may have confidence that no such casualty has happened. About the 9th or 10th of December we, at home, may assume that we shall hear of the success, or the reverse, of the Egyptian party as regards the recording of the actual passage of Venus; and not many days afterwards we may hope to have tidings from Christ Church, New Zealand. Rodrigues, the Sandwich Islands, and Mauritius, where Lord Lindsay has his observatory, must take a longer time to transmit their news, their nearest telegraph stations being more distant. Some months may elapse before we receive the desired information from Kerguelen's Land; but if the reports from all of the other stations named be favourable, we may be tolerably confident that the final settlement of the true distance of the sun from ourselves has been accomplished. During the last transit in 1769 the observers were scarcely prepared for the phenomenon they were called upon to watch, the black drop or ligament which seems to the eye to connect the planet with the sun not having been sufficiently taken into consideration. A fairly wide margin for error in calculating the results was left, owing to the fact that the time of actual visual contact was doubtful through this unlooked-for feature. The coming transit will have this uncertainty eliminated from its observation. Every individual member of the expeditions will have an accurate knowledge of what he is to look for, a model of the planet passing over the sun's disc having been studied by them for months beforehand.

A hundred years ago who would have predicted that a transit of Venus could be painted so faithfully and perfectly that the pictures from the different observing stations should be a means of checking the accuracy of the eye? Yet, such has been the advance of science, that the comparatively new art of photography does this, and is made the docile servant of the astronomer. It is expected that the photographs of the sun taken during the crisis will become most valuable records. They will settle the knotty point as to the true time of the planet's contact should any discrepancy arise between the notes of individual observers. We can scarcely suppose that such discrepancy will occur, but with the knowledge that the

nerves, even of the most experienced, may be upset at a critical time, we cannot be too thankful that the black art will give unerring registration. Perhaps the most significant feature of all, and one which will live in the history of science, will be the application of photography to the coming event. Its employment may give a distinct method of calculation to the astronomer hitherto impossible. A negative picture (according to the instructions promulgated for guidance) is to be taken every two minutes whilst Venus is in transit. The exact time when the small exposure (the hundredth part of a second) is given is to be recorded by the aid of chronometers. The size of the sun's image will be somewhere about four inches in diameter, and this will bear magnifying to some hundred inches. Roughly speaking, each second of arc will be represented by the thirteenth part of an inch, a length easily subdivided to a much more minute fraction. Thus, by means of the negatives a small portion of a second of arc will be capable of being recognized, and the change in position of the planet during every few seconds of time will be appreciable. The apparent distance from the sun's centre of Venus at any particular instant will be readily measured, and the comparison of two suitable photographs taken at different latitudes on the earth's surface will enable additional verifications of the solar parallax to be made.

The possibility of obtaining such a large number of negatives during an interval of four hours is the result of the growth of photography in the last few years. The impracticability of using what is known as the ordinary "wet process" is patent to those who practise the art-science; the likely result of the use of chemicals in a confined space for such a length of time being to produce asphyxia, or something approaching to it, in the operators. The "dry plate process" which has been adopted is one which will enable the photographic staff to prepare their plates days, or even weeks, before they are required; and it will be unnecessary to develop the images until after the critical time. In other words, the sensitive plates will be exposed on the 9th of December, and the heavy labour of developing them executed at leisure on subsequent days. The ingenious plan that has been devised for registering the time of contact is worthy of notice. Originated by M. Laissen, the eminent French physicist, it has been carried into practical effect by Dr. de la Rue and Mr. Christie. Astronomers are well aware of the rate at which Venus travels, and they can judge by the eye of the position she will occupy on the sun's disc to within a few seconds of time. If fifty or sixty pictures of the limb of the latter be secured at intervals of a second, a few seconds before the time when it is judged that contact will take place, the exact instant will be shown by an inspection of them. In practice a circular glass plate of from eight to eleven inches in diameter is prepared for receiving the solar impressions, and is placed eccentrically in the focus of the telescope to which the camera is attached. The light is totally excluded from it, excepting through a small fixed opening of about one inch high by a quarter wide, which can be closed at pleasure by a simple contrivance. The plate revolves round its centre, the revolution being stopped at certain points by a very pretty piece of mechanism; whilst the stoppage takes place a brief exposure is given through the aperture above described. An interval of one second elapses between each such exposure, and if Venus and the sun's limb be focussed on the part of the plate opposite the opening, a succession of pictures on the edge of the plate will be impressed. One of these will record where contact has been made or broken. It is believed that this will give even closer accuracy than can be expected from visual observations.

The recent purposes to which the spectroscope has been applied have indicated that this instrument can also be advantageously employed for deciding the moment of contact. The Italians will use it almost to the exclusion

of any other method, and we believe we are correct in saying that at some English stations it will be held as an auxiliary weapon of attack. From the latest accounts received from abroad, there will be over sixty stations planted in the two hemispheres, where keen eyes will be waiting for the 9th of December. With all the requirements of scientific apparatus at present under command, we cannot but surmise that 1874 will be marked by the successful solution of that problem which has been before the minds of astronomers from the earliest period of history.

## THE PRACTICAL PRINTER IN AMERICA.

### VIII.

#### CUTTING PAPER.

In the next chapter Mr. Hearn is at home as the practical printer, and gives some excellent hints on economical cutting up of paper:—

"*Cutting the Paper.*—In cutting up the paper for printing due regard should be given to the materials employed. In the first place, the fingers should be free from anything that will stain or soil the paper, and they should never touch the *sliced* side, but always the *back*. The hands should be perfectly dry, free even from any perspiration, for if this is not strictly regarded in the handling of the paper, 'finger stains' will appear on those parts of the paper with which the fingers come in contact. To guard against this, a rough crash towel should be suspended in a convenient place, and the hands wiped upon it as often as may be found necessary—say once in every five or ten minutes. An ivory newspaper cutter, about eight inches long and an inch wide, together with a suitable sized pair of shears, will be all of the instruments necessary.

"In cutting the paper for very large prints, such as 13×16, 14×18, 16×20, &c., the beginner had best (to obtain the right size) lay over the sensitive paper the proper size mat that is to be placed over the print when finished, and then cut accordingly. Considerable paper can be saved in this way, and printed in hard size.

"There should always be an assortment of different size mats in the printing room; one of each size will do, which should be kept expressly for this purpose.

"In cutting the paper for an 11×14 print, the length of the sheet is generally placed before the printer, and the paper bent over to the further edge of the sheet, and then creased, and thus cut into two equal pieces, one of which can be used for the contemplated print. I would recommend that instead of taking exactly one half of the sheet of paper, as described above, to take about *an inch more* than the half, so as to allow for any slight tear that may happen along the edges of the paper during the washing, toning, &c., and also so as to be sure of having the paper plenty wide enough for the different sized mats.

"I have seen some nice prints printed upon the exact half of a sheet of paper, which, when taken from the final washing (and the edges trimmed, being slightly torn), were then too narrow to be covered with the proper size mats, and had to be rejected; whereas, if in cutting this paper they had made allowance for this final trimming, the prints would have been saved. The rest of the sheet can be cut very well into sixteen or eighteen hard pieces.

"In cutting cabinets out of a sheet, fifteen is all that can very well be obtained, and to get that number lay the sheet on a wide table, or printing bench (with the length of it running from right to left), and divide it into three equal parts. By laying the cabinet glass on these strips of paper, and cutting the paper a little wider than the glass, five cabinets can be obtained from each strip, and fifteen out of the whole. These pieces will be plenty large, both in length and width; besides, this is a very convenient and economical way to cut the paper without waste.

"By a glance at the cut (fig. 1) it will be seen that the

size of the pieces will be  $4\frac{1}{2} \times 6$  inches, and consequently there will be more room for the width than there will be for the length. The edges of the width side of the paper

Fig. 1.

can be trimmed a little, as there is usually some little tear, or some other defect, that can thus advantageously be got rid of. Often when there are only a few cabinets to be printed, I take a quarter-sheet, and bend over the length of it to about three-quarters of an inch of the opposite side, crease it, and then cut with the paper-knife. You thus obtain a large and small piece; the smaller one of these can be cut into four cards, and the larger one can be cut in two, and thus obtain two generous size cabinets, or the printer can use the larger of the two pieces for printing the  $4 \times 4$  size. This is the way I obtain my  $4 \times 4$  pieces when I wish them.

"The beginner must remember that in bending over the length of a sheet of paper  $18 \times 22$  inches in size, the divided paper will be  $11 \times 18$  inches in size, which is termed, in the language of the printing room, half-sheet.

"To obtain the quarter-sheet, the length of the half-sheet is cut equally in two pieces, and then the size will be  $9 \times 11$  inches.

"A glance at fig. 2 will show that either a generous size

Fig. 2.

$4 \times 4$ , or a couple of nice cabinet pieces, together with four cartes, can be easily obtained from a quarter-sheet.

"To obtain thirty-two cartes, quarter the sheet, and divide each quarter into eight equal pieces.

"To obtain thirty-six pieces out of a sheet, it is necessary, for convenience, to first quarter it, and then divide it into three equal strips (fig. 3) taken from the length of

Fig. 3.

the paper. The pieces, as thus cut, will measure  $3\frac{3}{4} \times 9$  inches, which will answer admirably for the stereoscopic size. Each one of these strips of paper can be cut into three generous cartes, making nine out of a quarter, and thirty-six out of a whole sheet.

"Forty-two cartes can be obtained very neatly by laying the sheet before you (fig. 4), and dividing the length into seven equal parts; when done, each strip should measure  $3\frac{1}{4} \times 18$  inches. Now, out of each of these seven strips of paper there can be six pieces of paper cut, which will be  $3 \times 3\frac{1}{4}$  inches in size. The whole number of pieces will be forty-two. It will be seen that the size of the carte pieces

( $3 \times 3\frac{1}{4}$  inches) does not allow but a very little room for waste paper in trimming after printing, and thus it will be

Fig. 4.

found necessary to exercise some care in placing these pieces on the negative for printing.

"To obtain the forty-two card pieces from the sheet without waste, great care is required in the sensitizing of the paper to prevent tearing, and also to prevent silver from getting on the back of it; and in the cutting of it to use either the shears or the paper-knife with care, and do not tear the paper with the hands, as is very often done especially when the printer is in a hurry.

"In making out the above, I have considered the sheet of paper to be  $18 \times 22$  inches in size, but it is seldom that the sheet measures exactly this, for the length oftens measures from one quarter to one inch more, but never less, while the width is invariably the same. When this is the case, a little better margin is allowed in cutting the sheet up, which is a good thing, especially when a large number of small pieces are to be obtained from the sheet. Forty-two pieces is all that should be obtained from a sheet of paper which measures  $18 \times 22$  (or  $18 \times 22\frac{1}{2}$ , &c.) inches, because the pieces of paper are now as small as they should be with safe results to the prints, on account of bad edges, &c., which it is often necessary to trim after printing. There is a way to obtain forty-eight, and even fifty-two pieces of paper from the sheet, but I would not advise any of my readers to try to obtain that quantity, as there are many disadvantages connected with it that more than neutralize the benefits. The paper is sometimes cut up to the exact carte size, and then printed up as it is, thus saving the trimming of the prints after printing. This is, perhaps (?), a good way, but for the beginner it is very risky, because the paper will have to be placed exactly on the negative, or else the print will be worthless. Even to the experienced printer this is very difficult, because the greatest care and skill are required to do it as it should be done; then the inexperienced printer could not hope to do it successfully.

DIFFERENCES IN SOLAR HEAT.—In the abstract, by the *Scientific American*, of the papers read before the American Association for the Advancement of Science, Professor J. P. Langley is reported as saying that "there is a variation in both the heat and light, and probably also in the actinic force, of different parts of the sun. The difference is due principally, but not wholly, to difference in atmospheric absorption. It does not appear, as the result of experiments, that there is so great a selective absorption of heat in the lower regions of the sun's atmosphere, that, when rays come from the edge of the disc and pass through a greater proportional thickness of his atmosphere, the heat is filtered from them, and the light allowed to go through. We find that the heat falls so very rapidly toward the edge as to indicate a much greater thinness of the solar chromosphere than has been hitherto admitted. We appear to have been led to the conclusion that there is a local obscuration over the spot, very remarkable both in degree and kind."

## THE FORTHCOMING PHOTOGRAPHIC EXHIBITION.

FROM an announcement in our last, our readers have learnt that the exhibition of the Photographic Society will be held within a month of the present date, opening on the evening of Tuesday, the thirteenth of October, in the Suffolk Street Gallery, Pall Mall, a conversazione being held on the opening night in accordance with the custom of the last few years. Under existing circumstances, special effort will be required on the part of everybody concerned to make the forthcoming exhibition a success—perhaps, indeed, to prevent its being a failure; but if every one who has any duty to perform, every one who can use any effort or influence in relation to the matter, will put his heart into it, with a resolve that there shall be no shortcoming, success will be certain. The unhappy dissensions in the society wasted much time, and dissipated some enthusiasm which would have been well applied in preparation for the exhibition; the same circumstances led to the necessity of placing exhibition arrangements in new and less experienced hands. There will be no medals distributed; there has been great difficulty in securing a suitable room, and this has caused delay, and the delay has excited doubts and fears as to the exhibition being held at all: and none of these things, naturally, conduce to success. But the legitimate issue of all these should be an earnest resolve by every well-wisher of the society to aid in securing success. The time is short, but there is still time before the seventh of October—by which time all contributions must be forwarded to the secretary—for every photographer who has exhibited before, for every member of the society that can produce anything worthy, to prepare, and send in good specimens of the present capacity of the art. Whatever value may attach to other modes of action of the society, the value of its exhibition is beyond cavil. It furnishes from year to year landmarks of progress, standards of excellence, and stimulants to higher effort. It permits each photographer to test his own position, and to gain suggestions for improving it. It affords to every photographer the one priceless opportunity of seeing what can be done, what is doing, and what should be done in his art. The very effort to produce something worthy of exhibition which each con-

tributor makes is in itself a valuable education. The exhibition is, in short, at once instructive and delightful to everybody, except the few unhappily constituted persons who find gall and wormwood in everything connected with another's success.

That the exhibition furnishes one of the pleasurable anticipations of the year, there can be no doubt; and that it is a pleasure in every way connected with profit and advantage, there can be equally little doubt. Failure, or even falling off, would be especially disastrous, and also in some sense discreditable, alike to those who initiated and carried on the agitation in the society, and to those who suffered such agitation to interfere with the legitimate work of the society. Every one, no matter what his relation may have been to the late agitation, is concerned, therefore, to aid in avoiding failure or falling off. Nothing so readily promotes good feeling, nothing so efficiently cements it, as engaging together in good work, and we hope to see every trace of bitter feeling buried and forgotten in the exultation over one or more successful exhibitions. Without discussing the general desirability of giving medals at such exhibitions, we think every one will agree that it was wise to suspend the practice at the present, and so remove one possible bone of contention—one possible source of heartburning. The competition this time will be for no stake but honour; for no honour but public appreciation. Each will enter it challenging his brother competitor as

“— Brother should a brother dare  
To gentle exercise and proof of arms.”

It will be especially interesting and desirable under such circumstances, therefore, to see that there is no slackness or indifference in producing high-class work for exhibition, and showing to the public the real claims of photography to status and recognition. There is, however, very little time; and therefore the more need for energy. If the “sword be too short,” let each contributor “add a step to it.”

As our readers know, the competing pictures for Mr. Crawshay's prizes will form part of the same exhibition, being, however, hung all together in one part of the room. As these will consist of landscapes as well as portraits, they will doubtless materially add to the interest of the exhibition. Intending competitors for those prizes should remember that their contributions must be sent to the Suffolk Street Gallery not later than the seventh proximo; that they should be addressed to the Secretary of the Photographic Society, distinctly marked on the outside of the case that they are intended for the Crawshay Competition; and that a letter of advice containing all necessary details should accompany them.

The general arrangements as to the admission of members and their friends will be the same as heretofore. This exhibition will open with a conversazione, and will continue open for three weeks, from nine in the morning until dusk, and on Monday and Saturday evenings from seven to ten, to enable operators and others engaged during the daytime to be present.

## PHOTOGRAPHIC PROGRESS.

THE *Home Journal*, a high-class paper published in New York, has an interesting article on the progress of photography, based on a notice of one of the recent Conventions of the National Photographic Association. The Association, it remarks, “has now over twelve hundred members, with branches all over the land; and its last meeting was the most important ever held, the attendance of members being large, and the display of photographs remarkably fine. Considering how the old strife has given place to cordiality among photographers, and secrecy to open doors, it is evident that the American photographer is awakening to a sense of his highest needs |

So wonderful and great has been the growth of photography in this country since the late Professor Morse took the first sun-picture in America, in this city, that those who now practise the art are counted by thousands, while the amount of capital invested can only be estimated by millions of dollars. The photographer is now everywhere recognized as an artist; to be anything else is to fail to secure the patronage of an intelligent public. And it is plain that if they are the literal descendants of such men as Phidias, Michael Angelo, and Rembrandt, there must be a glorious accumulation of wisdom and experience worthy of their attention. Recognizing the fact that artistic education is the present all-absorbing and imperative need of the day, the photographers of the United States have organized for mutual improvement, and this is what renders their annual meetings events of so much importance to all who are interested in the development of art."

After referring to various important applications of the art, the writer proceeds:—

"Thoroughly trained operators are difficult to get, and the printing department often suffers for the want of capable assistants. Recognizing this latter want, the National Photographic Association has asked Congress for an appropriation of thirty thousand dollars for the establishment of a Photographic Institute for the instruction of pupils in the art of photography in all its branches. Why may not this be a new field of labour opened for women? With a suitable training it seems to us they might easily acquire the skillfulness necessary for printing photographs. And, instead of asking Congress to establish a school of photography, the better way would be for some one to found a chair of photographic art in connection with colleges already established, as at Cornell University, Vassar College, or the University of Michigan. The sum asked is so small, we think little difficulty would be experienced in obtaining it from private individuals. Girls need this employment more than boys, and if the door to it is not opened in any other direction, let the Cooper Institute or the Normal College of this city prepare the way."

The article concludes by giving an interesting letter by Professor Morse, remarking:—"The best way to note progress is to contrast the past with the present; and we cannot do this better than by presenting to our readers a never-before published letter from the late Professor Samuel F. B. Morse, written shortly before he died, to Dr. Fuller-Walker, the editor of *The Aldine*, in which he gives an account of the first Daguerreotype ever taken in America. The letter is as follows:—

"*Poughkeepsie, August 14th, 1871.*

"DEAR SIR.—In the spring of 1839, just before leaving Paris on my return home, I formed the acquaintance of M. Daguerre, the reputed discoverer of photography. The proposition to give him an annuity on condition of his revealing to the world his wonderful process was before the Chamber of Deputies, and had not yet passed the requisite forms. I learned from him that so soon as the bill was passed he had ready for publication the details of his process. I then requested that so soon as it was published he would remit me a copy of his work. This he promised, and accordingly, in the late summer or autumn of 1839, I received a copy, and immediately had constructed the apparatus as therein given in detail. Its first trial I made upon a plate of plated copper procured in a hardware store. It was about the size of a common playing card. I adjusted the apparatus at a back window on the stairway on the back of the University, and the object to be taken was the Unitarian Church, now a theatre, opposite the New York hotel in Broadway. The hotel was not then built, so that I had a clear view of the church. I was successful in obtaining an impression, although, owing to the impurities of the silver upon the plate, it was defective; yet it assured me that the process was genuine.

This, I believe, was the first Daguerreotype ever taken in America. With sincere respect, your obedient servant,  
To Fuller-Walker, M.D. SAMUEL F. B. MORSE.

## CAMPHOR IN THE PRINTING BATH.

BY WILLIAM BROOKS.

SOME time since, in these pages, I called attention to the use of camphor in the printing bath. It was Mr. Clemons who first drew my attention to it for keeping the bath free from albumen and colour, which answers the purpose admirably; and by using it I found that it had power of entirely doing away with blistering of the albumen. It seems to render the film of albumen quite porous, without injuring it in any way, and thereby letting the air or water pass freely through it.

What I wish to call attention to now is to correct the mistakes of several who have tried it, and have failed to gain the result required. I said, keep a lump of camphor floating in the bath (bottle). The reason of the failure is, that many have put a lump of camphor in the bottle (when they have been troubled with blistering), and just given it a shake and used it at once. That is not the slightest use: it takes time for sufficient camphor to be absorbed by the water before it will have the desired effect.

The best way of making up a new bath (forty or sixty grains to the ounce, according to the salting of the paper employed) is to place (say) half an ounce of camphor in half a gallon of distilled water, and let it remain for several days—it will improve the longer it is kept—to effect complete saturation; then use it to make the bath, and then always keep a lump floating on its surface (in the bottle), and by that means the solution is in a state of complete saturation. In my hands, by its use as described, blistering seems impossible.

I see by your impression of September 11th, in the "American Correspondence," Mr. Hearn, in his formula, strongly recommends it as a safeguard against blistering.

I think camphor may in many other branches of photography be pressed into service.

## ON THE ACTION OF COLOURS UPON BROMIDE OF SILVER.

BY DR. H. VOGEL\*.

IN the last issue of this journal I mentioned some criticisms made by Dr. Van Monekhoven upon my researches, and in consequence of these strictures I felt it incumbent on myself to forward to Dr. Monekhoven some bromide plates of mine, which showed most perfectly the action of the red and yellow light. My honoured friend and colleague thereupon sent me some spectrum pictures, which he had previously taken, together with the following letter:—

" . . . You will see from my plates that it is not necessary, in order to secure a picture of the sun's spectrum upon bromide of silver, to expose for minutes, but only for seconds, even with a slit which is ten times as narrow as your own.

"In the pictures forwarded by you, a double action of the light is quite evident, and I am surprised that an attentive mind like yours should have passed over the matter without having divined its course. The case is thus:—The light at first acted as usual—that is, in a very brief period (in your experiments perhaps in less than a second)—giving an impression from the violet as far as the bluish green. Then, at the end of several seconds, your collodion plate was attacked by diffused light, which suffuses the whole plate, and comes from the prism. Finally, the red and yellow rays of the spectrum acted as continuant rays, and here certainly the tinting of the film by means of corallin, &c., has played its rôle.

"In this sense, therefore, your discovery is a sound one. I hope that in this connection you will repeat the experiments of M. Beequerel, who has not observed the phenomenon that the sensitiveness of the film changes with its colour.

\* *Photographisches Mittheilungen.*

"I resume my view of the matter thus:—To secure a photographic impression upon bromide of silver, only a few seconds' exposure are necessary, even with a very narrow slit in the spectroscope. The violet, blue, and green rays act in this case, and, as I believe, quite independently of the colour of the bromide of silver.

"If, however, the bromide of silver is first of all exposed to diffused white light, and then to the action of the spectrum, the maximum of action will take place where the absorption of the colour added is greatest.

"It is in this sense that we must look upon the phenomenon, and if I can be of any use to you, I shall be very willing to repeat experiments in this direction. I authorize you, should you desire it, to publish this letter in your valuable journal.—Your friend,  
MONCKHOVEN.

"Ghent, July 11, 1874."

I am very willing to publish my friend's opinion on the subject.

As it will be seen, after an examination of my spectrum pictures, Dr. Monckhoven now regards my discovery as a sound one, only he gives another explanation of the phenomenon, drawing a distinction between creating and continuing rays. I expressed my opinion last year that such a distinction did not exist—that all rays are shown to be chemically active. Herschel found that red rays acted chemically upon salts of iron. Becquerel's assertion that yellow rays only are capable of exerting a continuing action which blue and other so-called chemical rays have started, is only a theory in explanation of certain appearances, which may be explained in a much more simple and easy manner without the assumption of the existence of continuing rays. Becquerel found out that chloride of silver or bromide of silver, if exposed for a short time to daylight, is then sensitive for yellow rays, which otherwise it is insensitive to, and for this reason he calls the latter rays continuing rays, because they are only capable of continuing the action of the white light. The matter, however, is to be explained in quite a different way. By the slight action of diffused light, sub-chloride of silver is produced, which is sensitive to the yellow rays of the spectrum, and it is no wonder, therefore, that a more rapid action takes place than usual.

When subchloride of silver is produced in a purely chemical manner, without the aid of light, and is exposed to yellow rays, an action will be at once apparent.

How weak Becquerel's theory on the matter is, is proved by the numerous experiments of extra-lighting, which Gaensli conducted in America. This investigator prepared plates which would allow of no chemical rays to pass, and which, by extra lighting, subsequently showed a slight action. The matter appeared quite right; but when, instead of after-lighting, a preliminary exposure was given instead, exactly the same action was obtained; in this case, therefore, the so-called continuing rays had not continued the action, but commenced it, and were, therefore, *rayons excitateurs*. After such a result as this, those who like may believe in *rayons continueurs*. I repeat what I have previously said, when a subsequent exposure acts at all, chemically-working light is brought into play, which adds to the action already commenced.

But even taking the case that red and yellow may act as continuing rays, I can easily prove that such an action has not taken place in my experiments, at all events.

If, for instance, Dr. Monckhoven's view were right, then my pure bromide of silver plates ought to behave as Becquerel describes. The former says that in his plates two maxima of action were to be seen, one in the blue and the other in the yellow. This is not the case with my white bromide of silver plates, for they show quite a uniformly gradual decrease in the sensitiveness of the blue towards the yellow and red.

Much less does Dr. Monckhoven's view harmonise with another phenomenon that I have not yet described. With the increase of sensitiveness for yellow or red by the

addition of colour to the film, the decrease of sensitiveness for the more refrangible colours goes on hand-in-hand. The theory of continuing rays cannot explain this phenomenon.

In the most definite manner, however, do my coloured plates show the fallacy of Dr. Monckhoven's idea. These demonstrate exactly the reverse of what he assumes. He says that at first the action of the violet and blue rays begins; then the action of the diffused light; then, for the first time, the action of the yellow rays, which continues the impression of the diffused light. The plates coloured with naphthaline red, however, prove as follows:—Exposure for a short time gives only an action of the yellow light, and of the blue not a trace; only after the exposure has been prolonged does the action extend to the green, and, after some time again, as far as the blue and violet; but the impression was much less vigorous than that of the yellow. Such facts as these prove beyond question that the action does not begin by means of the blue rays, and continue with the yellow. Indeed, it would be more logical, in this case, to term the yellow rays *rayons excitateurs*, and the blue ones *rayons continueurs*.

### THE INFLUENCE OF TEMPERATURE IN PHOTOGRAPHY.

BY LEOPOLD BACHRICH.\*

ABOUT light and its influence in photography so much has already been said that one may regard the theme as well nigh exhausted; but temperature is a subject which has been but seldom discussed, notwithstanding the many defects which are clearly traceable to it. These defects are to be found more often in some studios than in others, because, in some cases, the studio is situated on the ground floor, in a cool and even temperature, while in others it is placed on the roof of a tall building, where it is of course subject to every change of temperature. According to the degree of warmth, different defects are to be found, just as much in the cold months of winter as in the hot summer days, and these have all to be combated by the photographer.

The photographic phenomena during the cold season may be almost always removed by artificial heating of the room. A warmer temperature is maintained in the laboratory, and the temperature of the chemicals is in this way heightened. Most of my colleagues know what it is to place their bath and developer over-night in a warm (or, at any rate, temperate) locality, ready for use in the morning. But in summer time it is not so easy to combat the effects of temperature, and I will here enumerate such difficulties as I have experienced during the past summer, and the manner in which I have sought to overcome them, prefaceing my remarks with the statement that, as my studio is on the fifth floor, I am greatly at the mercy of the sun.

A very well known evil during hot weather is fogging upon the plate. To prevent this I place the bottle containing the dipping bath early in the morning in a vessel of ice, and add as much acid as it will bear. Acid can be added so long as the collodion film sticks to the plates on intensifying. I have found it very profitable to employ old silver baths as much as possible during the summer; those which have been put on one side in winter, as being too old, often furnishing the best results. I always have a few baths of this kind, and never use perfectly new ones, and need not fear fogging, even if there is no ice at hand.

After putting the prepared plate into the dark slide, I cover the back with a moist rag that has been lying upon a piece of ice, and is first of all well squeezed. To the developer I add one-third water, so that instead of twenty ounces there are thirty ounces of water to every ounce of iron. The iodizing of my collodion I modify in the summer so that iodide of ammonium predominates; under these

\* Photographische Correspondenz.

circumstances the film—even when it remains a long time in the slide—does not show dry spots very soon, and intensifying to any degree is unnecessary. The softness of the picture is not injured; but I recommend the employment of not too thin a collodion.

To the pyrogallic acid I add nearly double the amount of acetic acid that is usual. The plates should not be dipped into the bath too soon, but the ether should be allowed to evaporate thoroughly, even if the corners of the plate become dry, for there is usually sufficient margin upon the plate not to interfere with the picture. A trial plate will show whether you have waited too long or not. Too quick immersion in the silver bath brings about a number of streaks, and especially in those parts where the collodion has been applied, circular markings appearing one upon the other; and when the silver bath is too strong, as is often the case in summer, there are, besides, pinholes without number to be seen.

A second class of phenomena which, despite application of ice, has caused me much annoyance, and which was the more noticeable the higher the temperature, was the reversal of the shadows when intensifying. I mean that those parts of the negative which ought to remain clear and transparent became covered. After the intensifying solution (silver and pyrogallic acid) commenced to act, the margins of the plate began to colour where the collodion drained off. First of all a light yellow tint was perceptible, and then gradually this extended to the shadows of the picture, becoming more and more intense, so that at last they were of a dark brown; in printing, therefore, white patches are produced where the deepest shadows ought really to be.

Such a phenomenon as this is calculated to give the photographer—especially if he happens to be an inexperienced amateur—endless trouble, for he knows not how to help himself, and one plate after the other fails without his being able to divine the cause. Even laborious retouching is powerless to set matters right.

I am convinced that many of my colleagues who suffer from this evil, and do not yet know a method of combating it, will find my plan of operating afford a successful solution of the problem. The phenomenon is due simply to the alkaline nature of the water used for washing, and it is but necessary, therefore, as soon as one is troubled with the difficulty in question, to add to the water a little common vinegar, which will be found quite sufficient to overcome the difficulty. The water for use should be renewed daily, and a fresh quantity of vinegar added.

### ENLARGEMENTS.

BY A. HESLER.\*

No photographer can expect to make good enlargements on first trials, except by accident. To make a suitable transparency by any process, from which to make a good enlargement, requires the same care and practice that are necessary to produce a good negative. The conditions required are a structureless film, clear manipulation, just the right exposure and development to give all the detail, and no more. The appliances to make a transparency I will not describe, as they are so well known, having been published over and over again in nearly or quite all the treatises on the art.

Everything in readiness, we proceed to make the transparency; for this the regular collodion process is of course the most convenient, and the least trouble. The simplest and best way to attain good results (where the negative is the size you desire the transparency), is to coat your plates with your regular collodion (this and the bath must be so in harmony as to produce perfectly clear glass in the extreme high-lights); pass a small rubber band over each end of your negative from which you are to make the transparency;

place in your holder; against this place your coated and well drained plate for the transparency; close your holder, and place in your camera as if to make an exposure for a sitting, only use no lens. Take the front board and tube away from the box; extend the bellows to its greatest length; turn the box toward a white screen under your sky-light, or to the clear sky through an open window; draw your slide, and expose as long as your experience dictates, usually from one to ten seconds. After exposure, develop with a very weak iron developer, about one quarter the usual strength; or, better still, use pyro-developer made after usual formula, care being taken to have the silver used very acid with C. P. nitric acid (this will prevent fogging or stains). Clear up with hypo-soda, and wash thoroughly. If you have over-exposed your plate, the shadows will be too much developed—not enough contrast; if under-exposed, the detail in the high-lights will not be out. Remember this rule in all developing processes. For intense negatives over-time and use weaker developer; for weak negatives, under-time and use stronger developer. To those who have enough of this enlargement to do, and will become familiar with it, the Edwards process is, to my mind, the best that we have; but the following, in most hands, will be found quite as good, perhaps better:—Take good porcelain collodion, and proceed to coat your glass for transparency (the glass having been previously clean and albumenized) the same as though you were making a porcelain. Print from negative in usual way sufficiently, so that when toned and looking through the transparency, all the detail in both high-light and shadow will be seen. A suitable transparency made in this way will give an almost faultless enlargement. I have used also Carey Lea's dry process with success, and secured some very fine transparencies.

### PORCELAIN AND WATCH-DIAL PORTRAITS.

BY WILLIAM SHAW.\*

The porcelain glass should be selected with the utmost care. Watch-dials, of course, will have to be taken as they come. Wash your plate or dial in a solution of lye, then rinse with water, and place them in a moderately strong solution of sulphuric acid and water; wash thoroughly, and leave plates or dials in a dish containing pure water.

Prepare albumen solution as follows:—In a quart bottle put in some pieces of broken glass; drop in the white of an egg, to which add twenty ounces water, and one drachm liquid ammonia; shake thoroughly; let stand until settled, then filter through a very fine sponge. Albumenize your plate or dial, and set away on blotting paper, in some place free from dust, until dry. When dry, flow with collodio-chloride, which you will make as follows: In a bottle put one ounce of alcohol; add eight grains citric acid, eight grains chloride strontium. In another bottle put four ounces ether, and three ounces alcohol. Now, in a small mortar put forty grains nitrate of silver, which incorporate in the alcohol and ether by speedily and effectually triturating it before evaporation of the ether. When this is done, add fifty grains guu-cotton, and shake until dissolved. A few drops of water may be ground up with the silver before the alcohol and ether are added. Now add (in the dark room), a small quantity at a time, the solution of citric acid and strontium, shaking thoroughly after each addition. Let settle. Shake up the collodio-chloride half an hour before using. If, after a few weeks, the collodio-chloride shows lack of sensitiveness, add two or three drops liquid ammonia. After flowing plate or dial, and when dry, fume five to ten seconds.

*Toning.*—Wet your plate or dial with pure water, then pour over a weak solution of bicarbonate soda; wash thoroughly, and tone in your regular gold bath after your prints. Before toning the porcelain, add a few drops acetic acid No. 8, until blue litmus paper is reddened. Tone same as prints, wash, and fix in regular hypo bath.

## STEREOSCOPES.

BY J. H. B.

I HAVE never been able to ascertain why it is usual to blacken the insides of stereoscopes, and it appears to me to be a mistake to do so. In the common form, the light is admitted through a small window in the front part of the instrument. This window is only slightly above the picture, and only admits light from the front. The photograph, therefore, is in the best possible position for any roughness in the paper to be made unpleasantly apparent; the cavities, being lighted on one side and dark on the opposite, are distinctly visible, which would not be the case if the light was reflected, or, still better, admitted from all sides, or vertically.

It is only in viewing a transparency that any advantage is gained by the complete darkness of the inside of the stereoscope, and, as nine-tenths of the pictures viewed are paper photographs, it would be better to make the instruments adapted to seeing pictures of that description with the best effect.

## Correspondence.

## BLINDS IN THE STUDIO.

SIR,—Some time ago, I saw in the NEWS a system of working blinds in the studio, by Dr. Vogel. I worked that system formerly, but have discarded it, as I found it awkward to work, having to push the blinds aside with a long rod: it required the eyes of the operator to be directed to the blind to be moved, therefore the strong light of skylight striking the eyes of the operator makes it difficult to see the effect of the light on the sitter, so I devised the following, which removes that objection. The cost is trifling, doing away with spring rollers, and only requiring a rod length of skylight and a few pulleys. It is also very easy to work, as I can open or shut our whole window in less than half a minute. The rod which we used formerly at top of skylight for curtains to slide on we now use for blinds to draw over, as shown in diagram. Size of blinds

about two feet by length of skylight, with a seam at top and bottom to receive rod an inch by half inch, same as in foot of ordinary window blinds; a cord is attached to top of blind, and passed over rod at top of skylight, then through double pulley at eaves down through pulley on back wall, up through same double pulley down, through pulley at foot of skylight, attached to foot of blind, as shown. The blinds require to overlap each other two or three inches, as they are apt to shift a little from side to side in working. The side blinds are worked with a pulley at top and bottom of side light, with an endless cord and blind attached, as shown, with a thumb-screw through cheek of block to press on pulley, regulated so as to support the weight of blind when up.—I am, sir, yours truly, JOHN S. BURNEP.

## THE STATUS OF PHOTOGRAPHY.

SIR,—I think the ideas of your correspondent, "Palman qui meruit ferat," on the effect of prices on the status of photography, very croneous. Although a low price does not, as a matter of course, imply inferiority of quality, still I think it must be acknowledged that the tendency of low prices is certainly in that direction.

We will suppose the case of two photographers, the one working for just half the prices of the other: of course it follows that one will have to do double the amount of business to realize the same amount of profit, and, consequently, being more pushed with business, will have less time to devote to his patrons, and, consequently, be under greater temptation to scamp his work; whilst the other, having more time to devote to his sitters, the retouching of negatives, and the various branches of the art which require time and study, will be able to do so with less strain upon himself, and therefore with greater probability of success.

It is a well known fact that many people judge of an article—especially a work of art—more by the price than by its real intrinsic merits. In my practice I rarely meet with any who grumble at the price; far oftener I hear such remarks as these: "I would rather pay more, if by doing so I can have a better picture;" or, "I don't mind how much I pay if I can get a first-class carte," &c.; thus clearly showing that excellence and high prices are most naturally linked together in the public mind. Now, I do not for a moment dispute your correspondent's right to produce first-class work at barely remunerative prices, but I do think it foolish and unnecessary to do so, as I take it that, at the present time, both middle and working classes are quite able to pay a reasonable price for good work, and will appreciate it more for having done so; for, after all, a photograph is an article of luxury and refinement, and can scarcely be brought under the same rules as the selling of bread and cheese.

I think your correspondent is scarcely consistent with himself when he complains of "tobacconists, confectioners, fancy shopkeepers, &c." taking up photography, and then goes on to say that he does not "know in what way photography differs so essentially from ordinary business." A photographer should be a man of artistic taste and skill, education and refinement, and be possessed of a large amount of patience and numerous other virtues. Surely these things have their market value. But if the time comes, predicted by your correspondent, when the quality of work now done for 10s. shall be done for 5s., the common working man, as far as pay is concerned, will be in a superior position. The case of the doctor does not seem to me to be a parallel: his services are absolutely necessary; those of the photographer are not so. We never hear of such men as Sims Reeves, Vernon Rigby, Santley, &c., endeavouring to raise the status of their profession by singing for the public on the lowest possible remunerative terms. Nor did Sir Joshua Reynolds, Sir Thomas Lawrence, Turner, &c., shed lustre on their art by selling their productions at a price calculated to clear the cost of paint, canvas, and wear and tear of brushes. I can quite agree as to the importance of doing everything possible to raise the quality of our work, but cannot see why, at the same time, it should be advisable to lower the prices.—I remain, yours truly, LAWRENCE ELLIS.

New Street, Wellington, Shropshire, September 12th.

## A PHOTOGRAPHER'S TOOLS.

DEAR SIR,—I am anxious, as I have had many hints from many kind friends, to do something very small in return for their kindnesses to me as a beginner and lover of the art of photography.

There is an old saying that "He is a bad workman who finds fault with his tools." As regards photography, I dispute the dictum, for who can do good work unless his studio or tent be light-tight, or unless he has a basis on

which to place his camera (I speak of out-door work), which is both firm and portable?

First and foremost, he must have first-rate legs; second, he must have a good camera (and there are lots of them); and, of course, no man in his senses would attempt to copy nature or anything else without the best lenses he could procure. But however good these latter may be, they are comparatively useless without good firm legs.

I only began photography practically a little more than two years since, but I have made a study as well as an amusement of it. I compounded my own collodion and everything else, and I think I have perfected my own legs. They are very portable and light. One screw each raises or lowers them (one or all three) at will; they are so fixed at top that they can be moved anywhere bodily, without collapsing; and on the top of all is an arrangement which, once the legs have been properly levelled and firmly placed, the camera can be turned completely round without the possibility of any change of plane, so that a panorama may be taken without the least trouble, and without any danger of derangement of the relative parts of the complete circle. I have myself taken one of a half circle on five 10 by 8 plates.

My first legs were converted from a set of the ordinary triangle-topped tripod, doubling up in the middle, by a carpenter in Italy; but since I returned to England Mr. Morley, of Islington, has completed my ideas, and made me a second set, by which I can raise my camera to about seven or eight feet. My old legs do very well up to five or six feet.

I enclose you my first attempt at Rembrandtesque effect out of doors. Please accept the others. The names are on the back.—I am, dear sir, yours faithfully;

W. H. PARKYNS.

PS.—I must apologise for the very bad print I have sent you of the Countess Adiana. Lady Parkyns has given all the rest away.

Castle Bank, Reigate, September 11th.

[The effect of light and shade in the Rembrandtesque portrait taken in the open air is very satisfactory. The other prints sent are very charming.—ED.]

## Notes and Queries.

### PHOTO-MECHANICAL PRINTING.

SIR,—“Grenatine” desires some information with regard to “mechanical printing.” He cannot do better than follow the directions that have appeared in the NEWS and YEAR-BOOK. The Rochford printing press, invented and sold by a practical maker—Francis, of Rochford—and not likely to get out of order, is the thing he should obtain. Rollers, ink, and all necessary information can be obtained from the same source.

I may also mention that if Captain Abney would appoint some agent for the sale of his litho ink that can be used on plain paper instead of the usually prepared paper, he will do good service to “art and artists.”—Yours, &c.,  
OBSERVER.

### SKYLIGHTS.

DEAR SIR,—I am glad to see that you have opened a column in the NEWS for queries, as many tyros like myself may thereby acquire some benefit from the more experienced of your subscribers. There are a number of amateurs, I have no doubt, who are without a skylight to their room, and I should like to submit the following problem:—I have a room ten feet high, and lighted from two sides at right angles to each other. What are the best arrangements for portraits under the circumstances, and colour of background?—Yours most respectfully,  
G. THOMPSON.

## Proceedings of Societies.

### MANCHESTER PHOTOGRAPHIC SOCIETY.

THE meetings of this society were resumed on the 10th inst., THOS. HEYWOOD, V.P., in the chair.

The minutes were read and confirmed, and Messrs. Thos. Chilton and J. T. Chapman elected members of the society.

Messrs. Wade and Payne were elected auditors for the year.

Mr. JOHN BRIER, Jun., exhibited a series of excellent prints, chiefly from wet collodion negatives. All the skies were printed from beer and albumen negatives. Mr. Brier had not found that process very reliable.

Mr. ATHERTON exhibited a number of views taken by Mr. Kershaw, of Buxton, showing the capabilities of Ross's symmetrical lenses. All the negatives had been taken on wet collodion, and some of them, Mr. Kershaw said, had been kept three and a-quarter hours before developing, by simply wrapping the slide in a damp cloth.  
C. ADIX, Hon. Sec.

## Talk in the Studio.

NEW AMERICAN JOURNAL.—A new monthly journal has been commenced in Chicago which pays us the compliment to use our name, the *Western Photographic News* being the name of the new venture. It is the enterprise of Mr. C. W. Stevens, who is proprietor of a large photographic warehouse in Chicago. There is some promise of “go” in the magazine, from which we give some extracts elsewhere.

ENAMELLING PHOTOGRAPHS.—The peculiar effect of delicacy and brilliancy which characterizes a good photograph when finished by means of the collodion enamelling process has of late been generally recognized, and portraits so treated have become very popular with the public. Many photographers, as we constantly learn from the complaints of correspondents, do not succeed well in applying this enamel. A French photographer, M. Leon Favre, has recently opened an establishment in London where he undertakes this enamelling for the profession. We have examined a large number of specimens of his work in all sizes, admirably perfect in finish, without speck, blister, or defect of any kind, and possessing the most perfectly glossy polish which can be desired.

THE PHOTOGRAPHS OF THE PRINCE IMPERIAL.—The Correctional Tribunal of Paris has just been engaged in hearing a charge brought against M. Guérard, dealer in photographs, Rue de Rivoli, and M. Vallentin, photographer, Rue Méchain, on a charge of committing an infraction of Art. 22 of the decree of the 10th February, 1852. By the terms of that law no drawing, engraving, &c., can be published, exposed, or sold, without the authorisation of the Minister of the Interior. In the present case the incriminated articles were photographs of the Prince Imperial. M. Guérard had applied in due course for permission to introduce into France 300,000 chromo-lithographic portraits of the Prince, which were to be executed in Belgium; and of those he had received a hundred and fifty thousand. Those had been distributed in the provinces, and had given rise to the question addressed by M. Ernest Picard to the Government at the late sitting of the Committee of Permanence. But others, although unauthorised, had also been distributed, and the police, after some search, had discovered that they came from the defendants. At the moment the commissary entered the premises of M. Vallentin he was found pasting photographic copies of the portraits on cards. In his defence he said he was not aware that he was doing wrong; he had received an order from M. Guérard, who admitted the fact, and declared he was supplying them to M. Haentjens, who asserted that they were duly authorised, and he produced a letter from that gentleman, affirming that the Marshal President had himself given permission for a hundred thousand of those photographs. The advocate of the defendants declared that the object of the law was to prohibit portraits which bore emblems in such a manner as to indicate a pretender, but those in question had none, as the Prince did not set himself up as a pretender, and had no occasion to do so. The court found the accused guilty, and sentenced M. Guérard to a fine of 500*fr.*, and M. Vallentin to one of 100*fr.*, and further ordered the confiscation of the proofs and negatives.

A LUBRICATOR.—EY S. V. ALLEN.—To photographers using a burnisher I can recommend the following lubricator, which I have found all that can be desired:—Take four ounces alcohol, four ounces ether; mix in a twenty ounce bottle. With a sharp knife scrape up fine two slightly rounded teaspoonfuls of French soap; put the soap into the bottle containing your alcohol and ether, and give the same a

vigorous shaking. After sufficient agitating, add to the whole eight ounces of plain (uniodized) collodion; again shake thoroughly, and your lubricator is ready. To use, when your photographs are dry, take a very fine and very clean sponge, and apply the lubricator; apply to the whole surface of your picture. It will dry in a few moments, and they are ready for the burnisher."

To Correspondents.

ALPHA.—There will be no medals or prizes at the forthcoming exhibition, except those offered by Mr. Crawshaw for specific competition. See article on another page on the subject.

ONE IN A FIX is not quite sufficiently explicit in describing his troubles. A "white kind of deposit on the collodion film" is a somewhat indefinite account of a difficulty. This deposit may be fog from various causes, or it may be the matt silver, which assumes the form of slug-tracks and oyster-shells. We are disposed to think that, in this case, it is probably the latter. In either case it may arise from many causes; but the most common cause of the matt silver stains is the use of a horny, repellent collodion in too new a condition. Age in the collodion will remove it; or adding a little old to the new will be found beneficial. Great care in frequently washing the inner frames of the camera may aid in avoiding the difficulty, and always allowing the plate to rest on clean pieces of blotting-paper in the dark slide will aid you. 2. Crapiness in the collodion also frequently results from the collodion being somewhat thick and glutinous in texture, and sometimes from too much water in the alcohol used in making it. Crapiness is often the result, also, of unskillful manipulation. Care is required with some collodions, in coating the plate, to do it somewhat quickly, and keep rocking it to prevent the collodion film from forming into crapy ridges. 3. If a negative be over-exposed it will be full of detail, but flat and wanting in contrast. In such case the best plan is to intensify after fixing, and use rather more than less silver than usual with the pyro solution.

S. W. O.—Your work is exceedingly creditable to you. The medalion bust is the best of the three sent. The other two have excellent qualities, and are really very brilliant and fine, but are just a trace over-intensified, so as to leave the face with a trifle less softness and modelling than might be desirable. The printing is unusually good. So far as we can see, there is no need to increase the height at the eaves; there is a positive advantage in having the eaves low, inasmuch as when the eaves are high the junction of the side and skylight makes a break in the light just at a point where it is coming in the direction of the head of the sitter. There is no special advantage, for ordinary card work, in a wider room, except, sometimes, the convenience of working.

J. S. CLARKE asks how he is to obtain "that virgin-like whiteness which is sometimes seen on vignette portraits." We are a little puzzled as to his meaning. Perfect purity in whites should be attained in all prints if the operations are properly conducted. Any lack of such purity may be due to two or three causes, such as want of density in the whites of the negative, keeping the sensitive paper too long before toning and fixing, exposing it to light too much during the various manipulations, or the use of old or acid hypo. If our correspondent had sent an example of the imperfect purity of which he complains we might have given him more specific information.

G. THOMPSON.—We print your query in "Notes and Queries," as you wish. In relation to the best mode of producing portraits in a room lighted by two windows at right angles to each other, you have omitted an important detail in the matter: you do not state the size of the windows. You will probably find the best plan as follows:—If one window face the north, place the sitter one or two feet behind it, and two or three feet from it, facing a little towards it. If the other window be very near, it may require the blind partially or wholly pulling down; if at some distance, it will give a soft light to the shadowed side of the face without a blind. A grey background of medium tint. Print No. 1 is under-exposed, and produced in a bad light; No. 2 is produced in a bad light, lacks vigour, and seems a little fogged. It is not quite sharp, either from imperfect focus or movement in the sitter. No. 3 is best; but it might be lighted so as to give more relief and solidity.

C. ANTHONY.—We regret that we have not the address in question. HALSTED BROOK.—The possession of a copyright in a photograph secures to you the sole right to sell and publish copies. You can secure the copyright in any photograph you produce for your own purpose by having it registered at Stationers' Hall. Any photograph you produce to the order of a customer will require a written transfer or agreement with the customer to secure the copyright to you.

BOB.—We have published several descriptions of the solar camera in back volumes. You will find one on page 102 of our eighth volume. Unless you are skilful in such work you will find it wiser to buy than to attempt to make.

C. FERRANTI.—We are not in a position to speak authoritatively, and we do not know the extent to which the pictures in question are worked upon, having only seen two or three examples once for a few moments; but if they are, as Mr. Ferranti states, only spotted and glazed, they will undoubtedly be eligible for competition. The same conditions which were before announced will again obtain. There will be no ban upon a slight and legitimate amount of retouching, the judgment of the jury, we understand, being based upon the whole of the conditions and the sum of the results.

J. G. FULLER.—We are glad to hear of your restored health and sight. Thanks for the examples of your work, which are very interesting. We shall have pleasure in receiving a detailed article on the subject.

Several Correspondents in our next.

\*\* \* A little delay in some cases may occur in answering questions, owing to the Editor's absence from town for two or three weeks.

METEOROLOGICAL REPORT FOR AUGUST.

BY WILLIAM HENRY WATSON.  
Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

Date.	THERMOMETER.			THERMOMETER.			Direction of Wind at 9 a.m.

Number of days on which rain fell	—	—	17
Number of days on which no rain fell	—	—	14
Number of fair days on which it was sunny	—	—	8
Number of fair days on which it was gloomy	—	—	6

MIGRATION OF SWALLOWS.—Whilst standing by the edge of a pond here, on the evening of the 21st, I observed a number of swallows—I should say at least a hundred—congregated together, and flying round and round. I have only seen one or two since, so that it seems that they have been preparing for their departure to some warmer climate. This usually, however, takes place near the end of September. How is it they are leaving us so soon this year?

Wind S. and S.W. prevailed.  
Braystones, September 2nd.

## The Photographic News, September 25, 1874.

## PHOTOGRAPHY IN AND OUT OF THE STUDIO.

## A FEAT IN PHOTO-MECHANICAL PRINTING—TRANSIT OF VENUS: THE DEPARTURE OF THE LAST PARTY OF OBSERVERS.

*A Feat in Photo-Mechanical Printing.*—A striking example of the aid that photography may lend to the contemporary press is afforded in a recent number of the *New York Daily Graphic*. The daily issue of a large illustrated journal such as this, the pages of which are bigger, while they are quite as numerous, as those of the best illustrated weekly papers in this country, is of itself an object for wonder, and the nature of the cuts and engravings produced is generally of a high-class nature. Indeed, at first sight it is difficult to conceive how such a paper can possibly be produced at all, for the number of artists and engravers engaged on a publication of the kind would be exceedingly large, while the expenses thereof must be unusually heavy. The key to the problem is, however, soon found, for, on examination of the front page, we see on each side of the title a little engraving: one of a printing press, the other of a camera. The truth is, that the *Daily Graphic* has constant recourse to photography in the production of its illustrations, and does not, probably, engage half the number of draughtsmen and engravers which such a paper would have required ten years ago. Photography is employed both for securing sketches on wood direct from nature, as also for reproducing line sketches and drawings in photo-type. Sometimes, therefore, it takes the place of the draughtsman, sometimes that of the wood engraver. But the particular example, or feat of reproduction, it may be called, to which we particularly wish to draw attention, is a specimen of photolithographic work of unequalled excellence. The only pity is, that the labour was not expended upon a more deserving subject. The Beecher-Tilton scandal, with which New York has resounded for the past month or two, is placed fully before the public in the shape of fifty-one long columns of correspondence, consisting of all the letters that have passed between the parties interested, reproduced most sharply and clearly from the originals by means of photo-lithography. The series of letters have been slightly reduced by means of the camera before being transferred to stone, and this diminution in size gives the whole mass of writing a neatness and uniformity which it would not otherwise possess. At the end of the journal is the same matter in type; but one can well understand that those who feel any interest in the matter at all would much prefer reading the letters as they stand, for there is sometimes as much to be gathered from a person's handwriting as from the purport of his note. The reader may here study the neat, legible calligraphy of Mrs. Tilton, as also the vigorous, though somewhat scrawly, handwriting of Mr. Beecher, and the rapid hand of Mr. Tilton. But it is our province merely to record the high degree of excellence with which the half hundred columns of MS. has been reproduced, and the clean, sharply-defined character of the *fac simile*, which amply prove how very much can be done by photography if one has only the patience and perseverance to work out some of the many ingenious processes that have been made public. It is singular that in this country, where so many clever mechanical methods have originated, photo-engraving, or phototype printing, is comparatively unknown.

*Transit of Venus: Departure of the last Party of Observers.*—The last party to be sent out to observe the transit of Venus will leave London next week for Alexandria, with Captain Abney, R.E., in charge of the photographic work. Most probably, two or three stations in Egypt will be fixed upon, and Captain Abney will be in command of one of them, and superintend the spectro-

scopic, as well as the photographic, observations. With him go Captain Browne, late of the Royal Artillery, and several other gentlemen, besides a party of Sappers who are to act as photographic assistants. One of the chief points attended to in making preparations has been the drilling of those to be employed in the photographic operations, so that a clear idea may prevail as to the work to be done at the eventful moment; and the reason for starting so early for the different stations is, that sufficient time may be at hand to continue this drill for some weeks before the services of the staff are to be put into requisition. By adopting this system of discipline, it is anticipated that much more advantage will be taken of the time at the disposal of the observers, and that double the number of pictures will be taken by thus having a well planned division of labour, and a method of operating in which all the employes have been thoroughly drilled. It is Captain Abney who has organised this drill and systematic plan of operating. All the Sappers from the corps of Royal Engineers who have been detailed to assist in the English expeditions scattered over the globe have been personally instructed by him. Each photographer-in-chief has three of these drilled assistants, and we may expect, therefore, a goodly number of pictures from each station if only favourable weather prevails. Lord Lindsay's party sailed in his lordship's private yacht, which was expressly fitted for the purpose, the observers and assistants numbering thirteen in all. Although somewhat small for the long journey to be made, the vessel is in every other respect well adapted to the purpose, and the hospitable owner has taken good care to provision his ship abundantly for the eight months' enterprise. The Germans have been very active in the matter of observing the December phenomenon. In July last a German expedition set out for Kerguelen's Land, south-east of the Cape of Good Hope, where we, also, have a party of observers; and in the same month another body—among whom was Dr. Krone, the president of the Dresden Photographic Society—departed for the Auckland Islands. In the middle of August a third party left Berlin for China, travelling by Southampton, Alexandria, Ceylon, and Singapore, to Tsehifu. Dr. Vogel, of Berlin, was to have taken charge of the photographic work in this case, but pressing engagements kept him at home at the last moment. A fourth expedition will set out at the end of this month, whose destination is Persia, and this party is accompanied by Dr. Stolze, of Berlin, who was editor of the now extinct *Licht*, and president of the Photographic Society of Berlin. This last-named body will travel overland by way of Tiflis. All our own expeditions, with the exception of those destined for Egypt, have left some time ago.

## HOW TO AVOID UNNECESSARY WASTE OF TIME AND SILVER.

BY E. Z. WEBSTER.\*

THE developings and first washings of the negative are rich in silver, most of which can be saved by using proper means and care. The plan recommended in Anderson's "Skylight and Darkroom" is about the best, but some simpler method will answer very well. Any large vessel into which you can run the developings and first washings, where they can remain undisturbed long enough to settle, will answer the purpose. The iron in the developer is sufficient to precipitate all the silver held in solution, but it settles slowly. When the vessel is full, let it stand a day or two, and then decant what you can; filter the remaining liquid through a cloth or paper filter. Another, and perhaps the least troublesome plan, is to make a long conical-shaped bag of cotton cloth or some similar material, which can be suspended in a barrel by

\* Concluded from page 447.

tacking the open or large end of the bag around the upper end of the barrel, allowing the small end of the bag to reach nearly or quite to the bottom of the barrel (of course the barrel is supposed to stand on one end and the upper head is removed). The waste pipe should be inserted well up toward the top of the barrel; now let your developings and first plate washings run into the bag, which will act as a filter, and save all the silver, and when you have obtained sufficient precipitate to make it pay, you can reconvert it to a workable condition by simply submitting the precipitate to the action of muriatic acid, which will dissolve out the ferro-sulphate, and leave a residuum, which is pure silver, requiring only to be thoroughly washed and then dissolved in diluted nitric acid; the acid may be driven off by evaporation, or neutralized, when the silver solution becomes ready for use.

In fixing the negative some operators prefer to use cyanide of potassium, but hyposulphite of soda is most generally used; in either case a shallow dish or tray large enough to lay a number of negatives in face up, with solution enough to well cover the same, is the most convenient and economical. By fixing in this manner the solution becomes rich in silver, all of which can be recovered by the galvanic process; but if you do not like to fuss with a battery, and are in no hurry, you can immerse a piece of copper or a copper plate in the hypo or cyanide solution, three or four inches square, and let it remain; the pure metallic silver will be deposited upon the surface of the plate, and when desirable to do so you can scale off the silver, and reduce it with nitric acid, evaporate, or neutralize, and the silver solution is ready for use.

Of course I am aware that there are several other ways of recovering silver from the solutions above mentioned, but the plan here recommended is the most easily managed by the majority of operators. The chlorides, carbonates, &c., are also easily managed; but the sulphurets, &c., require brains and other conveniences which I do not propose to furnish. A great deal of silver might be retained in a workable condition by using a little forethought. For instance, suppose you obtain a large open-mouth bottle, or other suitable vessel, and place it in some convenient spot. Now, when you rinse out your negative bath-holder, pour the first rinsings into the bottle, and when you have done with a filter, just drop it, while wet, into the same bottle; do the same with blotting-papers, sponges, and, in fact, everything which becomes saturated with the negative solution. By constant additions the contents of the bottle gain volume and strength, and an occasional stirring will reduce the whole to a pulpy mass, which should be strained, and squeezed as dry as possible, and then the weak solution thus obtained can be strengthened with new silver, or by boiling down, and is ready for use either to renew an old or make a new bath.

By making the contents of the slop-bottle tolerably strong of nitric acid, the silver contained in old dry filters, clippings, &c., can be reduced and utilized.

The advantage of some simple plan of avoiding waste must be obvious to any one who will stop to think of the foolishness of "going around Robin Hood's barn" to save a mere fraction of the silver which he has made into a conglomeration which could be avoided with less trouble.

#### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

8. The following table contains a list of the various substances subjected to experiment. All these bodies allowed the less refrangible rays to pass, but cut off the rays of

medium and extreme refrangibility wherever absorption occurred at all:—

TABLE I.—Diactinic Power of Solids.

\* I am indebted to my friend Professor W. H. Miller, of Cambridge, for the opportunity of examining the diamonds and sapphires alluded to above. l was a slice of diamond bounded by cleavage planes from the Warburton collection. m a somewhat thinner slice from the same collection. A large octahedral diamond from the Humian collection. All these were colourless. The sapphire 24 was a large six-sided prism from the Brooke collection; that marked B was a smaller prism of a faint bluish tinge from Professor Miller's own collection. n is a colourless crystal of sapphire from the Warburton collection. I made an application to the trustees of the British Museum for permission to use some of the limpid specimens in their collection, but was informed that, even for such a purpose, the Act of Parliament forbids them to allow any mineral to pass off their premises. Mr. Maskelyne was kind enough to lend me a fine colourless topaz from his own collection.

producing an effect which may be compared to opalescence or turbidity in a liquid employed in the transmission of luminous rays.

(To be continued.)

THE PRACTICAL PRINTER IN AMERICA  
IX.

PRINTING-FRAMES, ETC.

In the matter of printing-frames, American photographers are ingeniously practical, and several forms in use there are unknown in this country. Mr. Hearn confines himself to a description of those he has found best.

*The Printing-Frames.*—For the purpose of printing from the negatives upon the sensitive paper, printing-frames are constructed. The sizes of these printing-frames vary according to the size of the negatives. The imperial and the common card negatives are generally made upon 5 by 8 glass; then the printing-frames intended for this size glass should have this dimension on the bed of the frame. The whole-size negatives should be made on either the 6½ by 8½, 7 by 9, or even the 8 by 10 size glass, and for the printing of them a larger frame is, of course, necessary, which should have (as in the case of the smaller frame) a bed of the same dimensions as the different size negatives. Besides the bed printing-frame there is also another kind of frame used, which is called the flat printing-frame.

It is absolutely necessary that the printing-frames should be made of some well-seasoned hard wood, as they are exposed in all climates and temperatures. The depth of the bed printing-frames depends on the particular use that the frame is to be put to. For instance, a certain kind of frames are made for printing plain or medallion prints, and another kind for printing vignettes.

"Now, in the latter case, it is essential that the frame should be made deeper than in the former, because, in printing vignettes, greater softness is thereby given to the prints if there is considerable space between the negative and the vignetting card frame.

"You ask, Why not make all of the frames deep, as they will be much more handy? Because that depth of the frames will cast a shadow over the impressions on the negatives if the rays of the sun strike them obliquely, and thus ruin the prints; but this may be remedied, and the frames all made quite deep, by placing them when printing up to the sunlight. This is not always advisable, however.

"In speaking of deep (raised) printing-frames, I refer more to small ones, as 5 by 8, 6½ by 8½, &c. rather than to the largest sizes, viz., 11 by 14, 14 by 18, &c.; for in the case of the common card and the so-called cabinet, we can obtain by far better vignettes by printing them by means of common cardboard of a suitable size and shape, opening and raised printing-frames, than we can with the wooden block; while, with the larger sizes, I prefer the nicely made vignette-frames. However, more of this will be written of hereafter.

"The backboards of the frames should also be made of well-seasoned wood, and the springs, which should be attached to them, should be made of good spring brass, and so arranged to them that they will give an even and gentle pressure to the negative when it is placed in the frame, and the backboard fastened in.

"The springs meet the backboard of the smaller frames in one place, which is generally the centre of the frame; but in the large frames they meet the backboard in two places, and, for convenience, are not attached to the backboard, but to the frame itself, swinging back and forth at will by means of the hinges.

"The backboard should have soft pieces of cotton flannel glued to it, napped side out, on that side, of course, which is to be placed nearest to the negative. This give a soft cushion to the backboard, which is a desirable thing. As

The photographic impression of each spectrum, in every case quoted in this table, commences at 96.5, and the number inserted in the table in the second column of figures indicates the point at which the most refrangible rays transmitted by the compound under examination ceased. The numbers in the third column of figures represent the length of the spectrum, the unit of the scale being one millimetre.

9. In the majority of cases of saline compounds in the foregoing table, the results given are those obtained by forming a saturated solution of the compound in distilled water, and decanting the liquid after it had become clear by standing. It is not advisable to filter in these cases, as the introduction of minute quantities of certain compounds—especially of some of organic origin—greatly impairs the transparency of the liquid to the rays which produce chemical action.

The solution, duly prepared, was then placed in a small trough made by cutting a notch in a piece of plate glass three-quarters of an inch in thickness, the sides of the trough being completed by thin plates of polished quartz, which were pressed by means of bands of caoutchouc against the ground surfaces of the plate glass. No cement was employed, and the trough was taken to pieces and cleansed between each experiment, a stratum of liquid 0.75 inch thick being used in each case.

10. In the preparation of the various compounds for examination much care was taken to employ the materials in a state of purity. In one or two instances, however, it has happened that an acid which usually forms highly diastinic salts has exhibited an anomalous and excessive absorptive power, although in combination with a base which, in other instances, furnishes strongly diastinic salts. Here some impurity, in quantity so small as to escape the tests in ordinary use, but sensitive to the action of light, has probably been present, and has impaired the diastinic capacity of the substance. Cases in which such impurity is suspected are indicated in the table by the mark (?) subjoined to them.

It may here be observed that the solution of a salt in water always to a certain extent impairs the diastinic quality of the liquid, however limpid the solution may be,

a general thing, loose pads are placed in the frame on to the sensitive paper, but there is no absolute necessity for this if there is one or more good pieces glued to the back-board. The printing-frames thus far described have consisted of two parts, the frame and the backboard; but there is another very good frame (see fig.), which

is very popular among printers on account of its convenience when printing the crescent line on the medallion prints, as well as for various other uses. Its construction is very simple, consisting of a flat piece of some hard wood, the width of which is cut into two pieces in such a way as to have one piece one-third larger than the other. The separate pieces are now joined together by means of a couple of small hinges.

"A button is fastened to the smaller of the two pieces. This button should be large enough to keep the two pieces together when it is buttoned. This arrangement will permit of the larger of the two pieces being lowered or not, according to the desire of the printer. The reason of this will at once be obvious.

"On the front part of the board, and at the lower part of it, two or three pieces of woollen cloth should be tacked, which will give the paper, when laid upon it, a soft, yet sufficiently hard cushion for the purpose required.

"The negatives are kept in place on these boards, if printing is to be done, by means of some spring brass with wooden feet, each foot (two in number) being made of a piece of wood two inches long, one-third of an inch wide, and about one-half of an inch thick.

"These feet are fastened to one end of each spring by means of some screws; they are so fastened that they will move or not, at the option of the printer. The other end of these springs is fastened to the lower corners of the board.

"The wooden feet are used for the purpose of keeping the pasteboard (attached to the vignette blocks) close on to the negative, as well as to have the broad surface of the wood on to the negative rather than the brass itself, as the latter is very dangerous to the safety of the negatives.

"Never use the common iron springs in vignetting, as they are very likely to slip and break the negatives.

"*Keeping Tally.*—There are various methods adopted for the purpose of keeping account of the number of prints obtained from the negatives.

"One of the best ways to keep tally that I have ever seen or used I will here give. It is both simple and convenient, and there is no need of any mistake whatever if the printer is attending to his business.

"There are many disadvantages connected with the other devices of keeping tally, and the greater part of these are the liability of mistakes occurring in one way or the other, and the inconvenient manner of keeping the tally.

"The materials used for this purpose are a soft lead-pencil and some strips of common erasable tablet. A part of the main printing-frame is cut away for this purpose, and that part should be the back part of the frame, so that, in taking a print off, the printer will be reminded to make a mark or tally for it, his attention having been

attracted by seeing the tablet. The necessity for cutting away a part of the frame is because the surface of this

Keeping Tally.

tablet should be below the level of the top of the board, for then it will not be rubbed and scraped by contact with other boards, and thus, in a very short time, ruin the tablet, which it would do if precautions were not taken to the contrary. This tablet can be glued to the board, or tacked with one-ounce tacks.

"It will be seen by a glance at the cut that *ten* prints have been printed from the negative in the printing frame, and when two more are printed the order will be done. When this negative is finished the marks on the tablet can be erased with a damp rag, and the negative placed away. Another negative is placed in the frame, the number of prints wanted are placed at the left of the tablet, and then this negative is ready to be printed, and the tally kept as before.

(To be continued.)

## PHOTOGRAPHY AT THE ROYAL CORNWALL POLYTECHNIC EXHIBITION.

### JUDGES' REPORT.

The following is the report on the photography at the last exhibition, the judges being Messrs. T. Hart, J. F. Benson, W. Naylor Carne, and J. F. Trull.

SECTION I.—*Professional.*—In this section the number of exhibits is very fair, and we notice with pleasure several new names, amongst whom are Mr. G. Cooper, of Hull, and Mr. F. Hudson, of the Isle of Wight. To the latter the judges have awarded a second silver medal for landscape, "Bonchureh Valley," No. 572. It is a very fine photograph, full of atmospheric effect, combined with soft gradations of light and shade. A second silver medal is also awarded to No. 564, "Bits in Devon," by Mr. W. G. A. Grant. It may here be favourably remarked that the softness displayed in these landscapes is seldom met with in the dry-plate process.

Messrs. Alfred and John Bool are awarded a first bronze medal for the charming "Ruins of Waverley Abbey," No. 577.

A second bronze medal is awarded for the beautiful landscape by N. King, No. 558.

For untouched enlargements, a first bronze medal is awarded to a charming head and bust of a lady, by Netterville Briggs (No. 609), the artistic pose of which, combined with the life-like expression, could not be surpassed.

In portraiture, the first silver medal is awarded to Mr. George Cooper, of Hull, for the beautiful portrait of a gentleman (No. 620), highly commended for its lighting, pose, and brilliancy of tone. The judges are much pleased with his grand display of pictures, and hope to meet with his name another year.

The first bronze medal is awarded to the "Painter's Studio," by H. Garrett Coeking (No. 611).

The vignetted cretaceous pictures are highly commended for their softness, and beauty in the manipulation.

"Oxen," by David Hedges (No. 565), is highly commended for sharpness and detail.

SECTION II.—*Amateur.*—In this section the judges have

awarded a second bronze medal to "A Study from Life," by Cecil Wray (No. 654).

Some successful transparencies on glass, by C. A. Ferneley, are highly commended for their brilliancy of manipulation.

## PHOTOGRAPHS.

BY CARL PRETZEL.

[THE fun of the following example of the imperfect English pronunciation of a German will probably strike English readers less than it does Americans, amongst whom a large portion of the inhabitants consist of German immigrants.]

Photographically shpeakin, der art of dookin picturs vas a complimented cases; but der more vat you lif der longer you fiud it out. Dhere ish no doubt of a possibility dot if der invention vas diskofered B.C., we might hafe had a goot picture of Atan and Efe, und a picture of Cain in der attitoot of shlewin his brodder Abel. Vat a beaudifull ting dot would hafe been, to have handed ub to our children. How like der dence it would oberate on der minds of der youth of to-day, und would teach em nefer to shlew dheir brodders, efen in fun. But der minds of dose days couldnd been developed yoost yet, or dhey might have seen how easy dot vas, for to sot shtill a couple minnoots, und look shteady at a shmall piece of paper, while a feller vas lookin a shmall box through at you. Dose winds vas pooty dull, und in dose days when old Humun vas chasing dot abble peddler ofer der economized shtreets, shtealiu his fruits, he couldnd afford to shtop und dook in, on his mind, dot which would gif some reflections back.

How much would mudder Efe hate gifen to had a picture of leedle Abel, after he got shlewed. Vell, I baed you she would yoost gif more as a teu toller greenbacks.

Efeu myself would like to hafe a photograph of my fore-fadder Efe, vedder it was "full-length" or "bust." I would willinly be "busted" to hafe one.

I would radder have a photograph of my frow, dhen hafe der old woman *herself*, because, dhere sots der image in all her nadif simplicidy. She got a shmile on her feadures, und her white hands all filled full mit a shilling pair of gloves. But of der inside out of der picture, mine Got! vat a change. Dot shmile dhen vas dhere yet, und dhem hands vas all full mit hair, und dot hair vas once mine. It vas now pooty seldom of my head.

Some phodographers could dook picturs so nadural, dot dhey vas much besser preferred dheu dheir orriginals. I hafe heard of some, dot der orriginal vas efen besser dhen der picture. But dis cases vas seldom.

Der attanced phodographer vill labor to got a heffenly shmile on der feadures of der belated damsel, und vill cofer der wrinkles ub on der face of der antiquated maiden. Ven he vas do dot successfully, he vas make more as a barrel of gold.

A x-eyed friend of mine ish in der pishness, und I called on his house, one day-times, to got ackwainded mit der vay dot de vas dook picturs. I oney shtop so long vat I could saw how it vas done, und so gwick I got me introduced to der chemicalities, I yoost shtart me right away gwick, der pishness in. I found me pooty gwick out dot der "bath" vas for der picturs, not for mineself, and dot after I had dook me one shwim in dot bath, I found me out, I dhen vas not cut out for a picture dooker. I vas learn, und had drank myself in, oney one shmall knowledge of der pishness, which proofed more of a detriment dheu good, on ackound I vas ignoronter of der ballance.

By my cidy, we hafe a goot many goot phodographers, und dhey dook goot picturs. But of em all I dink, so far vat I could see, dot Mister Chromo vas dook der best picture of any odder feller in der town.

I reckememper once dot I had a picture dooken. I vent on der place where dhey keeb picturs for sale. I asked der man dat I wanted to got a picture of mineself. I looked

me at all der faces dot vas hung ub, but I didnd see vas mine already. So I yoost told him dot I would go on annoder place, but dot man told me if I wanted "a picture I must sot for him." Vell, I say alrite, und I sot me down. Der teller dook his box und commenced der oberation. Yoost dhen a muskeedler come ply of my noze, und vas make me more bodder as a hundred tollars. I couldnd keep shtill; I vas blow him away, but he comed all der vhole back, und I got me so mat I kicked myself. Der picture got cooked, on a leedle vhole, und while I could saw me a goot resemblance to der muskeedler. Der oberator vas shwore it was a goot images of mineself.

## Recent Patents.

### BURNISHING PHOTOGRAPHIC PICTURES.

BY G. P. CHITCHELSON.

THE provisional specification which follows describes a press similar to Weston's Patent Burnisher, and was not proceeded with, we believe, because it was found to be an infringement of that instrument:—

"The object of this invention is the construction of a machine or apparatus for burnishing photographic cartes-de-visite and other pictures, thereby imparting to such pictures a brilliancy of appearance and depth of tone unattainable by other processes. This object is effected by the combination of a burnishing bar made of steel or other suitable material, and heated by a spirit lamp, gas jet, or otherwise, and a pressure roller, the carte-de-visite or other picture being placed upon the said burnishing bar and between the same and the roller, and moved by the latter to and fro over the said bar. Upon a stand or frame of cast iron or other suitable material I mount a plate of any suitable metal. Over this plate I place the aforesaid burnishing bar, which may be made of steel or other metal, or of any other suitable material. The top surface of said bar must be perfectly smooth and polished, and must always be kept clean. Below the aforesaid plate I place a gas jet or spirit lamp or other means for heating the burnishing bar; this bar and the picture being burnished, will be protected by the said plate from any smoke or vapour arising from the lamp or heater. Above the burnishing bar I place the pressure roller whereby the picture is moved to and fro over the said bar. This roller is mounted on a shaft which is provided with a suitable hand wheel or handle, whereby the shaft and roller may be readily operated. The surface of the said roller is roughened so that it will not slip over the back of the picture without moving the same. The said shaft is supported in bearings which are adjustable vertically, and are provided with set screws and springs, or other means whereby the roller may be caused to exert any desired pressure upon the back of the picture as the same is moved to and fro by means of the aforesaid roller.

### ARTIFICIAL LIGHT FOR PHOTOGRAPHY.

BY E. E. J. SELL.

THE following specification describes a highly actinic artificial light for night photography:—

"My invention consists in producing a new photographic light by burning bi-sulphide of carbon with peroxide of nitrogen. As means of combustion, I make use of an ordinary petroleum or other suitable lamp with circular wick, containing bi-sulphide of carbon instead of oil. Water or other cooling medium surrounds the bi-sulphide containing chamber to keep it (the said bi-sulphide) cool. The peroxide of nitrogen is contained in a metal, glass, or other gas holder, which may be lined with asphalt or other suitable material. The peroxide led to the centre of the circular wick of the lamp is caused to be uniformly mixed with the bi-sulphide by impinging against a cone placed with its apex downwards within the circular wick. A stop-cock is used to regulate the pressure of the peroxide, and means are provided to carry away the products of combustion. A reflector is used, when necessary, to direct and condense the light.

"Having thus described and ascertained the nature and particulars of my said invention, I claim, the improved means of said apparatus for taking photographs at night, substantially as set forth."

## PORTRAITISTS' ADDRESSES TO THEIR CUSTOMERS.

THERE is a great tendency in mankind, when any subject acquires a permanent interest in the mind, to get into fixed grooves of thought and expression. In relation to photography, it has become the almost invariable custom of its devotees, amateur and professional, to speak of the art as a sacred entity, the elevation and advancement of which was, or should be, the first, if not the sole, aim of every one connected with it. The cultivation of such a spirit has about it so much that is laudable that it becomes almost an ungracious, if not a dangerous, thing to question its absolute truth and rectitude. The pursuit of even an ignoble duty with a noble aim elevates the act and the performer. A lofty motive, as quaint old George Herbert finely says, "makes drudgery divine." And if every man worked as owing something to his art, both the art and the worker would gain. We may mention, *en passant*, an admirable illustration of the advantage of combining the ideal and the practical aims. Mr. H. P. Robinson once informed us that when he first entered professional photography he resolved that, without neglecting business, or disregarding the "pot boiling," he would strive to produce every year one or more important pictures which should show the pictorial capacity of photography, and so, as far as possible, aid in strengthening its art claims. The issue is known to photographers all over the world, and gold and silver—in medals, at least—have poured in upon him from wherever photographic exhibitions have been held, from Chicago to "India's coral strand." But to return to the question. It should not be forgotten, in referring to photography, that it is, after all, but a means to an end. With many amateurs it is simply a hobby, or pastime, the pleasure being found in the practice; with others it is pursued as an easy means of securing pictorial results; with others it is an aid to scientific study; but with the professional portraitist it is always practised for the very prosaic, very necessary, purpose of making a living. That is its primary purpose with the portraitist: if he fail in effecting this purpose, it is little consolation to know that he has, in some way, elevated or promoted the advancement of the abstraction of which he thinks as "the art."

It can scarcely be supposed that this phase of the subject has not been well considered by professional photographers generally; but it has not only been insufficiently

discussed, but it has been often totally ignored that with the professional photographer, as with every caterer for public taste—

"Those who live to please, must please to live."

Taking this aspect of the question, one of the first aims of the portraitist is to establish good relations with his customers. His final aim may be to please them with good work, and so secure their continuance and their recommendation. But he must get his customers before he can keep them. The display of excellent specimens in neat show-cases, always clean, fresh, and in good condition; the maintenance of an attractive establishment in good taste, and perfectly kept; and other obvious modes of securing the attention of the public, do not come within our scope for discussion here. Our principal purpose is to call attention to a few of the prospectuses or manifestos by which successful photographers introduce their establishments to the public. In every trade or profession, a card, a circular, a prospectus, or pamphlet is found necessary as an introduction to future customers; and probably in no case is a judicious combination of explanation, advice, and instruction of more value than it is in securing a good understanding between the portraitist and his sitters. A little pamphlet entitled the "Photographer to his Patrons" has already been adopted by many as a mode of popularizing their establishments; and we now propose to describe and extract from some similar little brochures issued by high-class photographers in this country and America.

Commencing at home, let us glance at the brochure of Messrs. Robinson and Cherrill, of Tunbridge Wells: a neat little pamphlet of twenty-four pages, in a dark green enamelled paper cover, with the title, name, &c., printed in silver. The title given to the little work is "Portraits and Pictures Produced by Photography and Art." The opening chapter is devoted to a brief essay on photographic portraits; this is followed by a list of their medals—three or four dozen—obtained at different exhibitions in various towns in England, Scotland, Ireland, France, Prussia, India, and America. A selection of a dozen somewhat lengthy reviews, or notices, from newspapers, magazines, and quarterly reviews follow; then a catalogue of published works, followed by details of styles in which work is done, and the tariff of charges. The "Few Words on Photographic Portraits" with which the little work opens is devoted chiefly to some brief explanatory observations on the capabilities of the art at the present day. "There are few of the educated public," it is remarked, "who are not familiar with the general facts as to the history and character of photography; but its developments, modifications, and improvements during late years have been so numerous and important that only the most skilful of those who have studied it as a science, and cultivated it as an art, have kept abreast with the accumulating discoveries upon which the production of the highest degree of beauty, truth, and permanence depend.

"The general impression in the public mind in regard to photography is, that it is a quick, easy, cheap, and moderately truthful mode of securing likenesses; that these likenesses are never flattering, rarely even doing full justice to the original; that they are not works of art; and that they will fade. This impression, although by no means true of photography in its best phases, is unfortunately justified by a large proportion of the productions of *soi-disant* photographic artists. The greatest bane of photography has been the unfortunate facility with which a slight knowledge of it could be acquired, affording opportunity for the ignorant and unscrupulous to commence the profession of portraitist without the art-training necessary to produce pleasing portraits, or the scientific knowledge to secure any degree of permanency in their works; and thus the impression has gained ground that photography was a mechanical method of securing resemblances, the

transient character of which could scarcely be regretted, because they fell so far short of being true works of art.

"The prolonged study and practice of photography by a trained artist, and the resources placed at his disposal by recent discovery, give a control over the agencies he employs little short of that possessed by the painter over his colours and canvas, and photography becomes in his hands, not a mechanical operation, but a plastic art. His faculties, trained to perceive the most beautiful or characteristic aspect of his sitter; and his apparatus, guided by his scientific experience, combine to produce at once the truest and the most pleasing portrait; his artistic skill enables him to secure grace and ease in the arrangement, life in the expression, and delicacy and vigour in the pictorial effect; whilst the resources of modern photography afford to him, versed in its latest discoveries, the power to give an enduring character to his works, and free them from the stigma of fading away.

"A recent writer in a *Quarterly Review* has remarked:— 'It cannot be doubted that photography has many pictorial offences to answer for, and if its art-claims were to be judged by the productions of eight-tenths of the self-styled "photographic artists" who multiply travesties of humanity, they would assuredly be found wanting. Every form of awkwardness in position, every style of incongruity in accessory and *entourage*, has been exhausted, every canon of art studiously outraged. Even the special claim of photography to accuracy has been ingeniously destroyed by mismanagement of light and shadow, upon which form depends, by the use of bad lenses and worse manipulation, and by the exaggeration in the tendency in photography to mistranslate colour.' This is the stigma which has attached to the art by its practice in un instructed and incapable hands.

"But the same writer continues:— 'The photographer can stamp the impress of his mind upon his work, and in proportion to his artistic culture will be the beauty of his work.

It is not merely in the distinctive arrangement and accessory, in the management of pose and lighting, or in the attention to expression which is apparent, but in the pictorial feeling of the whole, that this is manifest.

Without falsifying, photography can ameliorate if it be in the hands of an artist, whilst it may easily caricature when it is in the hands of one ignorant of art.' The same writer adds:— 'The fact is, that a good photograph has a truth of its own, rarely belonging to the highest effort of the limner; and the term has become idiomatic in our language, that a faithful transcript of a thing is photographic in its resemblance.'

There is in the pamphlet a curiously studious omission of any instructions to sitters as to costume, time of sitting, or other points which commonly form the staple of a photographer's address to his sitters. We presume that the intention of the portraitists is to imply that they make no conditions about dress, but are content to deal with each sitter in his habit as he lives. Some costumes are certainly more suited for effective portraiture than others; but it is nevertheless often doubtful wisdom to do anything which fixes the sitter's mind upon his dress, or tempts him or her to make any modification of the costume commonly worn. On the subject of prices (which scarcely comes within our province to discuss), we may remark that the scale here seems to hit the golden mean. A correspondent in our pages recently very ably protested against the notion that price was an invariable standard either of value in the work or status in the worker. Possibly it should not be so; but, nevertheless, with the public it will generally be regarded in this light, and, within limits, it inevitably must be so. Good work demands time and care as well as skill; and the expenditure of time and care militates against low prices. Natural skill may cost nothing, but it always possesses a high market value, and cannot often be had in conjunction with low prices. Further, although the exaction of high prices does not

necessarily give status, the possession of good status has a commercial value, and enables the holder to secure good prices; hence good status and good prices are at least associated. In the scale of prices before us, as we have said, we find the happy medium: sufficiently high to pay for good work, but no exorbitant fancy charges based upon a high reputation. We make an extract to show the charges for everyday work.

"Cartes-de-visite, twenty for one guinea, ten for fifteen shillings; additional copies, one shilling each; cartes-de-visites, vignettes, twelve for one guinea; additional copies one shilling and sixpence each; cabinet portraits, eight for one guinea; additional copies, two shillings each; cabinet portraits, vignettes, six for one guinea; additional copies, two shillings and sixpence each; imperial portraits, size about ten inches by eight inches, under glass, one guinea and a-half; additional copies, half a guinea; gold frames for the imperial portraits, half a guinea and eighteen shillings; large portraits (the head about five inches) in oval with dark ground, size of picture about nineteen inches by sixteen inches, five guineas; additional copies, one guinea each; gold frames for ditto, one guinea to one guinea and a-half."

An interesting feature of the little pamphlet we must note before taking leave of it. Our readers may remember a curious and interesting article by Mr. Robinson in our pages on the various allusions by English poets bearing application to photography. This little pamphlet is enriched by quotations of a similar character, with a selection from which we conclude the present notice. On the title-page we have the following from Shakespeare:—

"Nature is made better by no mean,  
But nature makes that mean, so o'er that art  
Which you say adds to nature, is an art  
That nature makes."

Each page is headed with something similarly appropriate: thus—

"The glorious sun  
Stays in his course and plays the alchymist."—*Shakespeare.*

"Shine out, fair sun, till I have bought a glass,  
That I may see my shadow as I pass."—*Shakespeare.*

"For I have heard it said,  
There is an art which shares  
With great creating nature."—*Shakespeare.*

"Be keen in catching likenesses."—*Tupper.*

"Drawn by the powerful sun."—*Shakespeare.*

"As our art is not a divine gift, so neither is it a mechanical trade, Its foundations are laid in solid science."—*Sir Joshua Reynolds.*

"Yet I doubt not thro' the ages one increasing purpose runs,  
And the thoughts of man are widened with the process of the suns."  
*Tennyson.*

"Start into light, and make the lighter start."—*Rejected Addresses.*

"And looke at last up to that sovaine light,  
From whose pure beames al perfect beauty springs."—*Spenser.*

"The best in this kind are but shadows; and the worst are no worse if imagination amend them."—*Shakespeare.*

"Art may err, but nature cannot miss."—*Dryden.*

"Sounds which address the ear are lost, and die  
In one short hour, but that which strikes the eye  
Lives long upon the mind, the faithful sight  
Engraves the image with a beam of light."—*Dr. Watts.*

"How little is the cost I have bestow'd  
In purchasing this semblance of myself."—*Shakespeare.*

"Blest be the art that can immortalize."—*Cowper.*

"By the operation of the sun."—*Shakespeare.*

"The shadowed livery of the burnished sun."—*Shakespeare.*

"When with one virtuous us touch,  
The arch-chemic sun, so far from us remote,  
Produces, with terrestrial humour mixed,  
Here in the dark, so many precious things,  
Of colour glorious, and effect so rare!"—*Milton.*

Perhaps nothing in the range of literary coincidence could be more apt in its application to photography than these lines from Milton's "Paradise Lost."

## THE VOGEL-MONCKHOVEN CONTROVERSY.

It is agreeable to find a controversy such as has been going on between Professor Vogel and Dr. Van Monckhoven, on the subject of the sensitiveness of bromide of silver to the less refrangible rays, conducted in a spirit of courtesy and good will on both sides; and now that the matter seems practically at an end, it must be gratifying to all that the worthy experimenters are, if possible, more amicably inclined to one another than before. We may sum up the matter in a few words. It will be remembered that Dr. Vogel asserted that by tinting the bromide of silver film, he had made it as sensitive to the yellow and red portions of the spectrum as it is, under ordinary circumstances, to the blue and violet. Dr. Monckhoven, from experiments he conducted, and which he described in a paper to the Photographic Society of London, was unwilling to accept this assertion of Dr. Vogel, and to corroborate the statement, therefore, the latter forwarded, both to Dr. Monckhoven and to ourselves, impressions of the spectrum taken by himself, in which the red and yellow lines were shown.

In the last number of the NEWS it will be seen that Dr. Monckhoven fully acknowledges that Prof. Vogel has obtained impressions of the red and yellow portions of the spectrum. Dr. Monckhoven, however, believes the impressions to be due to the action of continuing rays. The light, he says, must have acted upon the sensitive plate as usual in the first place, giving an impression from the violet as far as the bluish green; then the plate was attacked by diffused light coming from the prism. "Finally, the red and yellow rays of the spectrum acted as continuing rays, and here certainly the tinting of the film by means of coralline, &c., has played its rôle." In this sense he admits Dr. Vogel's discovery to be a sound one, *the sensitiveness of the film changing with its colour*. Dr. Monckhoven believes, however, that the violet and blue rays always act independently of the colour of the film, and that it is only *after* the coloured film has been exposed to diffused daylight that the red and yellow rays come into action at all. Dr. Monckhoven, it seems, therefore, admits that the yellow and red rays do act upon the coloured film, but he will not accept Dr. Vogel's theory of their action.

Dr. Vogel disbelieves altogether in the matter of continuing rays, and certainly brings some weighty evidence against the theory. He believes *all* rays to be chemically active. When he exposes one of his white bromide plates for a brief period, he does not obtain only a slight impression of the blue portion of the spectrum, as would be the case if the action commenced there; nor does he find two maxima of impression in the blue and in the yellow; on the contrary, there is "a uniformly gradual decrease in the sensitiveness of the blue towards the yellow." Again, he finds that the *increase* of sensitiveness for yellow or red by the addition of colour to the film goes hand in hand with the *decrease* of sensitiveness for the more refrangible colours. Far from being *rayous continuuateurs*, Dr. Vogel thinks that the yellow rays should be termed *rayous excitateurs*, for when a plate coloured with naphthaline red is exposed for a short time only, a slight action is to be seen in the yellow part, but of the blue not a trace. Only after some time does the action extend to the green, and thence to the blue and violet; but the impression of these latter is never so vigorous as that of the yellow rays.

## THE IRON DEVELOPER WITHOUT ALCOHOL.

A DISCUSSION has recently taken place in some of the Continental journals as to the omission of alcohol from the iron developer. Herr Fritz Haugk, an able occasional contributor to the *Photographische Correspondenz*, advocates the use of alcohol, and indicates what he believes serious difficulties arising from its omission. Writing to that journal, he says:—

"In a recent number of the *Photographisches Archiv* I noticed an article by M. Dallas in which it was stated that alcohol added to the developer exerted a baneful influence on the latter. It rendered the developer slower in its action, and often caused flat, grey, silver stains. To counteract these defects M. Dallas recommended that alcohol be altogether avoided in the preparation of the developer, and that acetic acid be employed instead. Finally, M. Dallas remarked that it is surprising how brilliant and vigorous negatives are secured in this manner.

"Acetic acid is certainly a body which, like alcohol, facilitates the mixture of collodion with water, and one part is quite capable of rendering six parts of the developer suitable for application to the collodion film. I do not, however, look upon this substitution of acetic acid for alcohol at all in a favourable light, for after a few days a developer thus prepared loses its properties, and a fresh addition of acid has to be made. Again, a developer which contains a large quantity of acetic acid becomes weaker in its action, for a considerable proportion of acid added to the developer retards its action. In a fresh developer this is scarcely noticeable, but is apparent as soon as it becomes decomposed, and attains a red tint. As, however, this retardation may be regarded as due to under-exposure, I will illustrate my meaning by an example.

"About a fortnight ago I prepared two developers, one consisting of—

Iron ... ..	7½ grammes
Water... ..	240 "
Acetic acid ... ..	15 "
Alcohol ... ..	15 "

The second solution I made up of the following proportions:—

Iron ... ..	7½ grammes
Water... ..	240 "
Acetic acid ... ..	45 "

And no alcohol.

"These two developers on the first day gave almost identical results; but after the lapse of about six days, the second one worked much more slowly. Whilst No. 1, after eight seconds, gave a perfectly detailed negative, three seconds more were necessary to produce the same result with the other. In these experiments the plates had been sensitized during the same period, and the time that lapsed between sensitizing and developing was also equal. This must, of course, be specified, otherwise it might be inferred that the cause was elsewhere to be found. The exposure in both instances was also the same, a clear sky without clouds being at hand at the time.

"Besides the point alluded to, another of importance may be mentioned, viz., that acetic acid is more expensive than the best alcohol; and in conclusion I may state that the defects attributed by Dallas to the spirit are never to be feared, provided pure alcohol is employed for the purpose."

As we have for many years past omitted alcohol from the iron developer, and have also advocated its omission, a few comments on Herr Haugk's experience may be desirable. In the first place, it is by no means necessary to add excess of acetic acid as a substitute for alcohol; and the example which Herr Haugk gives is one that no intelligent photographer would dream of adopting. In testing the developer with alcohol omitted, he makes a fifteen-grain iron solution, and adds at the rate of ninety minims of acetic acid to the ounce of developer, and finds that it rapidly loses energy. No wonder. At the expiration of six days a lengthened exposure was necessary to secure a detailed image with this developer. But very few photographers keep a developer six days ready for use. Some prefer to make a fresh developer with crystals of the iron salt every day. Many more keep ready a saturated solution of iron, and make the requisite quantity of developer day by day, or as it may be required; and in such case a very slight excess of acetic acid would be

sufficient to secure the easy flow of the developer, and its ready admixture with the silver solution on the plate, if anything like fair manipulative skill be employed. But in our own practice we have preferred the addition of sugar. A twenty-grain iron solution, with ten grains of fine sugar—crystallized candy sugar by preference—and fifteen minims of acetic acid, to each ounce, will give capital results, flowing in an even, slow, steady wave over the plate, and requiring no alcohol whatever. We believe alcohol to be generally useless, and often mischievous, causing stains and spots. Its use has for years been so common that it has been adopted as a matter of course. We believe that, after fair trial of its omission, no one will return to its use.

THE STATUS OF PHOTOGRAPHY.

BY GEO. HOOPER.

THE numerous and interesting letters that have been published on this subject during the last two months demand a few words in reply, in order to induce photographers generally to come to some definite conclusions, and to arrive at some practical results.

In the first instance, I beg to say a few words in answer to your last correspondent upon his reply to a letter by "Photographer;" and then, secondly, to draw attention to the practical remarks of Mr. Bovey; and lastly, to suggest means whereby this desirable end may be attained.

The time for talking is now over, and the time for action arrived. Why not appoint a committee of practical men to consider the subject fully, and draw up a scheme whereby photography as an art (if not a *fine art*) may be placed in a more honourable position? This is not only desirable, but practicable. Both the letter of "Photographer" and his confrère are wide of the question. There are professional art photographers, and commercial photographers; the one class tries to turn out pictures full of artistic merit, and the other takes a very fair class of photograph, and although it does not contain the art qualities of the former, yet is perfect as a photograph, and all that an uneducated public expect or (at present) demand. That photography, like everything else, will always, as regards price, be governed by the law of supply and demand, is no doubt a fact; and that some very fair photographs are even now turned out at five or six shillings per dozen may also be a fact; but neither fact at all affects the question we have in hand, namely, how can the status of the art generally be raised?

Mr. Bovey has made a practical suggestion, worthy of serious consideration; namely, that to all who are eminent in the art should be granted a diploma, obtainable in the same way and manner as "R.A." is conferred on dons in the painting art. So "F.R.P.S." might be granted to men of proved ability in the photographic art. This would be a degree worth working hard for, would give increased interest to annual exhibitions, and would inspire confidence in the public. Of course, to obtain such a desirable end, it is all-important that the system of granting diplomas be the most perfect that can be devised, and that a committee of professional photographers shall decide who are worthy of honour. The suggestion that a professional photographer of undisputed merit should be president of such a society or committee is good. It only remains to arrange the details of such a scheme to carry out the idea. The chief rock to avoid is the danger of being too profuse with such diplomas. These should be granted entirely upon merit, and, in order that all aspirants might be tried upon equitable ground, would it not be practicable to erect permanently a studio, with all necessaries for all the various processes connected with the art, and compel such aspirants to produce (say) some four or six negatives, and prints therefrom, in such studio, entirely unaided by a second party?

This brings me to say one word more with regard to the

suggestions on the above subject made in my letter inserted in the NEWS of June 15th, as to the necessity of a general conference of photographers; of a combination of societies and interests; of a system of annual exhibitions, soirées, and conferences in different towns; of one recognized organ for all the societies, and a general interest and participation in the profits of annual exhibitions. Let medals only be given for new discoveries of importance, and diplomas only for extraordinary merit. Will Mr. Bovey kindly publish his ideas with respect to my suggestion in the NEWS of June 15th, and say whether at such a conference the question of granting diplomas might not be discussed with profit? Many would come forward with the necessary assistance, and out of the existing societies a very good committee of eminent professional photographers might be formed to carry out the plan suggested.

ON VARNISH.

BY D. D. (BELGIAN SUBSCRIBER).

OF all the varnishes I have tried (and I have tried many), the best are certainly the following:—

First.—For professional photographers who may require to print a great number of prints from the same cliché:—

Weber's Formula.—Alcohol	...	...	100 parts
Gum lac	...	...	100 "
Common resin	...	...	32 "
Turpentine	...	...	32 "

I put the shellac into the alcohol, and let it dissolve without heat, for the reason that the waxy precipitate will be easily eliminated thus (as stated by Mr. A. Hughes, YEAR-BOOK 1871, page 74). To the clear solution is then added resin and turpentine. This varnish must be employed with a little heat applied to the plate.

Second.—For amateurs and photographers who do not use their negatives for a great number of impressions:—

Benzine	...	...	100 parts
Resin dammar	...	...	10 "

These I have used many years, and never found any trouble therewith. My negatives do not crack, nor peel, nor are destroyed or injured in any way.

In 1872 I communicated the formula to my friend, Mr. Leon Rommelaere, Lecturer on Photography at the Museum of Arts and Industries at Brussels, who, after trying, found it so good that in his conferences on photography in 1873, he recommended the formula as the best he ever tried. He added that he had communicated the formula to the War Department of Belgium, and that it had been since that time in constant use there with success and satisfaction. I report this as testimony of the good quality of the formula.

Third.—Coloured varnish:—

Spirits of wine	...	...	100 parts
Benzoin	...	...	10 "
Red, orange, or dark blue aniline	<i>quant. suf.</i>		

This formula served me for my experiments on the influence of coloured mediums on the colour of the prints.

When applied with heat, it gives a very hard and brilliant surface. When applied cold, it is matt, and takes retouching well.

MOONLIGHT PICTURES.

BY DR. J. SCHNAUSS.\*

As but little appears to be known in the matter of moonshine photographs, a few words on the subject may not be out of place, as such productions have been seen somewhat frequently of late, at the Vienna Exhibition and elsewhere. Some people have believed that such pictures were really secured by means of the light of the moon, because they possessed a peculiar greenish tone. Of course such an idea

\* Photographisches Archiv.

is altogether inexcusable in people who know something about negatives and the printing process, however much the uninitiated may be deceived; but as an interest has been awakened in the matter, I will mention how these kind of photographs may be produced.

In the first place, we must remember that there is a great difference between moon photographs and moonlit landscapes. The first—that is to say, photographs of the moon—are of course in existence, as every astronomer and photographer knows. On the other hand, to take a landscape illuminated by moonlight would be a knotty problem, and, under any circumstances, we think, it would be impossible to secure a picture which would have artistic pretensions.

According to Dr. Krone's experiences, the power of moonlight is as 1 to 6,000 compared with a dull winter's day or magnesium light. It is necessary, therefore, in order to produce moonlight effects, to have recourse to artificial means, and the following process will be found to answer:—

The landscape which is to appear illuminated by moonlight is photographed in bright sunshine with a very short exposure, so that strong contrasts are obtained and very deep shadows. The sky of the negative is covered or rendered opaque, and then a vigorous print is taken upon greenish tinted albumenized paper. The green paper is of the same kind precisely as other tinted albumenized paper, which is largely used for portraiture. Or if this tinted albumenized paper cannot be obtained, then the print is secured on ordinary white paper, and the picture afterwards rendered of a greenish hue by means of water colour or dye. When an impression of the landscape has been obtained, this is protected by a mask, and then into the sky portion is printed a cloud negative, showing the orb of the luminary. A suitable mask is contrived by cutting out the outline of a print from the same negative, and placing this as a shield over the landscape impression.

As in many moonlight pictures the outline of the luminary is to be seen, it stands to reason that the disc has also been secured by artificial means.

[As in most moonlight pictures the moon is shown, the operator must remember that the shadows should fall towards him; for this reason it is well to take the landscape rather late in the day, with a declining sun, the effects of which may be shaded from the lens in some degree, if found to interfere too much with the picture.—Ed. P. N.]

### LIGHTING FOR PORTRAITS.

BY L. G. BIGELOW.\*

So much has already been written on this subject, that a feeling of embarrassment controls me in introducing it again to your readers; but feeling also that herein is the great need of the majority of the fraternity, and that it is indeed the key to success in portrait photography, I am induced to write a short article under this head.

The whole system of lighting a subject for a photographic portrait is contained in the following sentences:—The light must be properly balanced; the exposure sufficient to bear out the lighting; and the development regulated to the exposure. No one of these three items can be in error without destroying, with mathematical certainty, the perfect result. You may approximate and produce good pictures, but not the best. Place a sitter under an uncurtained light, and even in the most favourable position possible, and we at once see that one side of the face is in very strong light, and the other in very strong shadow. We can hardly see any detail in the shadow, except we squint the eyes and shut out the volume of light which confuses our vision (as it will also that of the lens); then we see some of the details. Now take a large card-

board, and hold it to the side of your face nearest the direction from which the light comes, and hold it also in such a manner that you see only the shadow side of the sitter's face, and observe how, at the instant the light side of the face is obscured by the interposition of the card-board, the shadow seems to lighten and become transparent. We perceive at once, from this experiment, that the shaded side of the face is not in the deep shadow it seemed to be, but that the force of contrast caused it to appear so; and, practically, for all purposes of photography, it is so, for we cannot make our lenses squint. You will see by this that by balance I mean an even illumination or light so managed that the contrasts shall not be white and black. There is no pure white on the flesh of the pictures of our best painters, and the high lights of our best photographs are always kept many tones below white; but, for all this, the shadows are so managed, by being kept transparent and full of detail, that they seem much lighter than they really are.

Now draw your curtains until the proper balance is obtained. By these contrasts, in connection with the position, we may develop or obscure many characteristics in most faces, and in the good judgment used in doing so is shown the true artist; for it is a feeling, a thought, a sentiment, a glimpse of the inner man which he is trying to give to his picture, and unless the heart is interested, the result will be as lifeless as "Mark Twain's Mummy." If the light be obtained by curtaining down, and thus gaining balance, the exposure must be full; on the other hand, the same result may be obtained by an exposure of one-third, more or less, under a large light, because stronger illumination may be used without increasing the ratio between the brilliancy of the high lights and proportionate density of the shadows. Under all lights the operator cannot obtain this balance by both methods, for if the light is already small, the only way left is by reflection, and by curtaining down an already weak light, and making the exposure very long, to get the required details in the shadows. Hence I am partial to large lights, which require less use of the curtains to temper and control them. They give always sufficient diffusion, an ender possible any degree of strength obtainable by smaller and more direct lights. I think, as a rule, at least three-fourths of the operators in this country expose their plates too short a time in the camera to get the best results. The stronger the contrasts in your lighting, the longer must be the exposure of your plate, to blend and soften the lights, make transparent shadows, and give fine modelling and middle tint to pictures. It is like the use of a blender to the painter in oils. If used with skill, it produces on a too crisp, hard picture an enchanting softness, without destroying strength and character; but in unskilful hands the result is insipid and lifeless. Now, in lighting your sitter, remember you hold in your hands an equivalent power equal to the blender of the painter, and try to regulate the exposure of your plate to the degree of strength used in the lighting of the subject. Before you flow the developer over your plate, remember all the details of your skylight and camera work, so that at the last moment you may not ruin, by a too strong or too weak development, what otherwise was well nigh perfect.

### Correspondence.

#### STEREOSCOPES.

DEAR SIR.—Your correspondent "J. H. B." seems to have "hit the right nail on the head" when remarking on an imperfection in the ordinary construction of the lenticular or refracting stereoscope. He says that by the ordinary method of admitting the light from above, or by a reflector in the close box system, "the photograph is in the best possible position for any roughness of the paper to be made unpleasantly apparent."

\* *Photographic Mosaics.*

This observation is quite correct, and I am at a loss to imagine why a skeleton form of the instrument (admitting light on all sides) has not met with universal adoption. The best construction, in my opinion, is that invented by Prof. Oliver Wendell Holmes, which has a shale or dark screen for the eyes, all the other parts of the instrument being left freely open. I have an American stereoscope of this pattern which can be held in the hand, or screwed to an upright support, and this appears to be at once the cheapest and best form yet introduced. Something similar is made in England, but it lacks the leather hood.—Yours very truly,  
JOHN SPILLER.

TO AVOID PINHOLES IN THE NEGATIVE.

DEAR SIR,—In your last Friday's issue Mr. E. Z. Webster recommends a plan of turning the bath over to avoid pinholes in the negative, as he explains by two figures. We enclose you a plan we have used successfully for a number of years for the same purpose. We have a box made so that the glass bath fits exactly inside, as shown in fig. 1, which is ready to receive the plate. On the box are screwed pieces of wood shaped as the figs. 1 and 2; when

the plate is immersed in the bath, we have nothing to do but place on the lid, and tilt the box over on the other slant, as shown in fig. 2. The top edge of the plate then drops against the side of the bath, and, as the collodion side is down, and the glass side up, any dirt that may be in the bath must of course drop on the glass instead of the collodion, thus doing away to a great extent with dirty plates.

Having had the above in use for many years, we can recommend it as a "perfect cure" for pinholes caused by dirt in the bath.—Yours respectfully,  
Blackburn, Sept. 21st. WOLSTENHOLME BROTHERS.

THE CRAWSHAY PRIZES.

DEAR SIR,—I have to call your attention to an error in the announcement signed by Mr. Friswell, which appears in last week's NEWS, relative to the Crawshay prizes.

No. 3 Portraiture Prize will be given for heads not less than 4½ inches from the top of forehead to bottom of the chin. Heads half an inch over 4½ inches will be disqualified.

All pictures forwarded to the Exhibition to compete for the prizes must be marked on the front, "Crawshay Competition."—Faithfully yours,  
H. BADEN PRITCHARD.  
War Department, Woolwich, Sept. 23rd.

Talk in the Studio.

COLLODION FOR RESTORING BURNT DOCUMENTS.—Many of the papers charred in the great fire at Chicago are said to have been made readable by pouring collodion over them. It forms a thin transparent film, and dries in a few minutes. The printing or writing can be read through this film.

PHOTOGRAPHIC GALLERIES IN CHURCHYARDS.—The Shrewsbury Burial Board finds itself just now in a curious difficulty. It appears that a practice has grown up in the town of affixing to the tombstones in the cemetery the photographic

carte-de-visite of the person buried beneath. The exhibition attracts the curious, who, in their efforts to get near the illustrated tombstone, walk over the grass, to the detriment of the beard's property. 'By allowing the grass to grow long, and then cutting it,' the board realize as much as from £20 to £30 a year, and consequently view with the gravest displeasure this new manifestation of mourning. The deterioration of the graveyard hay crops is, of course, a very serious matter. But there are other considerations that make the threatened new fashion one which it is eminently desirable should be nipped in the early bud. In some minds there is probably a feeling of revolt against the desecration even of an unfamiliar graveyard by turning it into a photographic gallery, through which the curious may roam on fine Sunday afternoons. There is no doubt that, as far as the bereaved relatives who have thus adorned the borough cemetery are concerned, the exhibition is well meant, and is born of the conviction that a passing stranger would be glad to pause and look for a moment upon the counterfeit presentment of one who, perchance, filled a large space in their life. Different persons have diverse ways of expressing an identical sentiment. Some cherish the memory of their dead solitarily in their hearts; others, it appears, take out one from a dozen cartes de-visite of the departed, and paste it over the tombstone. The subject is one which is not to be argued on its merits, and on which hard words may not be said. But we are free to make the observation that it is the duty of a local burial board carefully to guard its sources of revenue, and that grass which, allowed to grow long and then cut, brings in from £20 to £30 a year, is worth looking after."—Daily News.

A TIGHT WOODEN BATH HOLDER.—This may be made by merely pouring hot asphaltum varnish (such as is used for gravel roofs) in the inside and out again of the wooden baths; enough will adhere to make a perfect holder. I have used such an one for about a year. It is all right; but a better one can be made of wood (pine is as good as any other) bolted together and dipped in the hot varnish, so as to be coated both inside and out. The wooden bath has the advantage over all others, because it is light, will not break, and is so very easily made.—Bulletin.

SUN OBSERVATORY.—Nature states that the German Government has determined upon the erection of a sun observatory upon a large scale at Potsdam, Drs. Speerer and Vogel having been appointed to undertake the telescopic and spectroscopic observations. The directorship offered to Dr. Kirchhoff was declined by that gentleman, as he was unwilling to leave Heidelberg.

THE FIRST OBSERVED TRANSIT OF VENUS.—The rare phenomenon of the transit of Venus across the disc of the sun, which will attract all scientific eyes on the 4th of December next, was observed for the first time in history under rather touching circumstances two centuries ago. According to a memoir recently issued, a young student named Horrocks had devoted himself, with true scientific ardour, but without any instruction, to the study of astronomy, and had calculated for himself that a transit of Venus ought to occur on a certain 24th of November, when the extant authorities had announced that none would take place during that century. Poor young Horrocks was curate of a little village named Hoole, near Preston. The 24th of November proved to be a Sunday, and the hour when he expected the transit that of his evening service, for the performance of which it was impossible for him to find a substitute. As he wrote to his only friend and fellow-student, a young man named Crabtree, he watched the sun, now clear, now clouded, from dawn till the afternoon, and then, as he could not forsake his solemn duty for such "an ornamental pursuit" as astronomy, he sorrowfully went to his little church and got through his duties. When he returned, lo! the clouds had all cleared away, and the image of the sun, reflected on the paper he had prepared, showed the small round black spot of the planet impinging on its disc. In the midst of his ecstasy Horrocks had sufficient command of himself to make accurate observations, which have since been the base of much useful astronomical calculation. But the career thus brightly opened, and which promised such scientific triumphs, was very shortly arrested. Horrocks died suddenly, at the age of twenty-two.—Echo.

LEAF PRINTS.—A correspondent of the English Mechanic gives the following hints on leaf printing:—"The bichromate of potash photographic process gives but a faint picture, even after lengthened exposure to the sun. The image may be

reddened by a dilute solution of nitrate of silver. Blue leaf prints are obtained by floating paper on a strong solution of ferriyanide of potassium, commercially called the red prussiate of potash. They are fixed by simple washing. By Obernetter's process, using salts of copper, pictures may be obtained in different tints of deep red and violet, with intermediate shades; but five different solutions are required, and the process, though not difficult, is rather tedious. Leaf prints of the greatest beauty and delicacy may easily be made by amateurs by the ordinary processes of photography on paper, scarcely any utensils being needed besides those found in any household. Make a solution of sixty grains of nitrate of silver and sixty grains nitrate of ammonia to the ounce of water. Float pieces of albumen paper, obtainable at any photographic supply store, on this solution for half a minute or a minute; pin up to dry in the dark. When dry, lay the paper on a thin board, the leaf on the albumen surface, and upon this a pane of glass. Fasten all together with spring clothes pins, and expose to the sun till the darkened albumen paper begins to show a metallic marbling; then remove from the glass, wash, and immerse in a solution of chloride of gold. For a ten cent sheet of albumen paper, eighteen by twenty-two inches, a grain and a-half of chloride of gold is needful. Dissolve in a pint of warm water, add a teaspoonful of salt, and a little chalk to remove the acidity; leave the washed leaf prints in this till they have assumed a pleasing shade (ten or fifteen minutes will be sufficient); then immerse ten minutes in a solution of hyposulphite of soda, two ounces in ten of water, remove, and wash thoroughly; if possible, leave over night in running water. These prints are very pretty. In experimenting with them, I obtained beautiful results by soaking them in aniline dyes; the colour does not show on the black ground, but the leaves shine out like exquisite paintings on ebony. The entire expense for chemicals (excepting the aniline colours) is \$2.50 for this process; this will be enough for twenty square feet of pictures.

## To Correspondents.

WM. CROSS.—The office for the registry of copyright is the Stationers' Hall, Ludgate Hill. All registrations must be effected by the photographer, or some one on his behalf, personally, as the authorities there decline to receive instructions by letter. The fee charged at the office is one shilling, and one penny for the proper form in which to enter details. The term of protection is during the life of the author, and for seven years after his death. The simplest plan, if you have no agent in London, is to send a copy of the photograph, with full instructions, such as you will find detailed in our YEAR-BOOK for 1863, to our Publisher, together with eighteen penny postage stamps to defray fee and portage. He will attend the office, and see the registrations effected for you.

J. DAVIES.—The best material for mounting prints on thin cardboard, so as to avoid cockling, is glue, or the mounting material sold by Marion and Co. The great object is to avoid using anything containing much water. Glue when in a state for use contains less water than paste, and Marion's material contains a good deal of alcohol in place of water.

J. T. L.—Card portraits will, we believe, be admissible to the exhibition, and, we presume, on the same conditions as last year, which restricted the contributor of cards or cabinets to one frame of twelve pictures. Mr Crawshaw offered, besides the prizes for large portraits, four prizes of £25, £12, £10, and £5 respectively for the best three landscapes not less than 10 by 8, and second best; and for the best landscapes of any size, and second best. We cannot ensure answers to questions reaching us later than Wednesday evening until the following week.

ARTIST.—There is nothing in the official letter of the secretary about coloured work at the forthcoming exhibition, and we have no information as to whether the exhibition committee, who have the arrangements in hand, have come to any determination or not. Last year it was determined that coloured work should not be admitted, and we presume the same conditions will obtain this year.

F. R. M.—Tea as well as coffee has been used as a dry plate preservative. M. Davanne some time ago recommended its use as a final wash in the collodio-albumen process in place of gallic acid. After the second process of sensitizing and thoroughly washing, the plate is coated with an infusion of tea and sugar thus made up:—

Water	...	...	...	500 cents. eub.
Tea	...	...	...	20 grammes
Sugar	...	...	...	25 "
Alcohol, 368 strength	...	...	...	25 cents. eub.

W. STREET.—See a letter on the subject of your note.

NORMANDY.—We scarcely think that the Channel Islands could be profitably visited during the winter months by a professional landscape photographer. The climate is mild enough, both in Guernsey and Jersey, but there are cutting winds sometimes, with sleet and snow, which have quite as hurtful an action upon the trees and vegetation as the cold weather in this country. Moreover, there are not many subjects at hand of sufficient interest for publication. There is the rocky bridge between Upper and Lower Sark, called the "Coupé," Elizabeth's Castle, and some quaint old towers, all of which an amateur would feel an interest in depicting; but we fear a professional photographer could scarcely make the journey pay its expenses. In some parts of Devonshire and Dorsetshire, and the back of the Isle of Wight, there are spots of a less wintry aspect to be found, but we should hesitate before advising a professional photographer to pass three months in any district whose avowed purpose was to secure photographs for publication as a paying speculation. Landscape photographs are taken so well and cheaply by local photographers, that one's productions must be exceptionally good to secure a sale. A visit to the interesting towns of Belgium and Holland might be undertaken, perhaps, with advantage, and there are many scenes of Dutch winter life worthy of depiction.

G. D. S.—The lenses of your half-plate camera are probably for portraits, and are therefore ill adapted to copying purposes. To copy full-size, the camera must be drawn out to twice the equivalent focus of the lens. If, therefore, the focus of your lens be seven or eight inches, the length of camera necessary is at least fourteen or sixteen inches. Most half-plate cameras only allow of making reproductions a fourth of the diameter of the original.

2. You do not describe the nature of your instruments. A rectilinear lens is generally employed for copying purposes. 3. Most photographs sold are copyright, and may not, therefore, be reproduced. The same may be said of pictures in the *Graphic*, *Illustrated London News*, &c. Only the other day *Punch* objected to its pictures being copied by photography, although, in this case, they had been reduced to very tiny dimensions.

J. CORDELL.—We should think that your pinholes arise from a mechanical, rather than a chemical cause. Is there any dust in your dark room? Do you employ a camel-hair brush to wipe your plates before applying the collodion, and, if so, is it kept in a clean place? Try your friend's bath again, in his own studio, but with plates of your own cleaning, and see if the defect still appears. You will then find out whether it is the dark room, bath, or plates that are at fault.

L.—Try plate paper, such as lithographers use. This is much better adapted for the preparation of the bichromate invisible photographs than ordinary bibulous paper. It is unsized, and therefore allows the bichromated gelatine to be as fully absorbed as ordinary filter paper; it has, however, a much better surface, and its texture is more dense.

BEGINNER.—The glare in copying may be prevented, to a great extent, by placing before the transparency a sheet of ground glass, which breaks up the light. If the transparency is a carbon one, the gelatine in the thicker portions of the image sometimes acts in a most vexatious manner, globules of the matter forming minute condensers of light, and thus imparting a solarized action to some portions of the reproduced negative.

Several Correspondents in our next.

## PHOTOGRAPHS REGISTERED.

- Mr. R. J. LITTLEJOHN, Kingston-on-Thames,

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. MILITARY BALLOONS AND PHOTOGRAPHY—GLUE FOR MOUNTING—A NEW DICTIONARY OF CHEMISTRY.

*Military Balloons and Photography.*—The subject of reconnoitring from balloons is again attracting the serious attention of our military authorities, and there seems at last some chance of the difficult problem being satisfactorily solved. The thing to be done is to ascend to an elevation sufficient to observe the tactics of an enemy, and rapidly note these either on a plan or map, or, better still, by obtaining an instantaneous photograph of the scene. Photography has hitherto received but limited application for taking observations from balloons, although two or three successful attempts have been made to secure pictures with the camera. A photograph of the city of Philadelphia, taken from a balloon, we remember to have seen, which gave an accurate, if rather blurred, depiction of the geometrically built town, a sketch such as would have been invaluable for war purposes, supposing the place to have been occupied by the battalions of an enemy. Nadar, the great Paris aeronaut and photographer, who was appointed one of the chiefs in the postal department during the Paris siege, to superintend the *ballon monté* service, has recently been successful in securing a balloon photograph which, Sir Charles Wheatstone informed us, was of a most successful character. The difficulties to be overcome (and these have militated hitherto against the undertaking of photographic observations from balloons) are the gyrations and restless motion of the machines in the air, which render any exposure but the most rapid quite impossible. The extreme buoyancy of the balloon and the action of the air currents are almost insuperable difficulties in the photographer's path. Our military authorities have lately, however, had under their consideration a balloon different to those ordinarily employed, and its slow and steady ascent will, no doubt, diminish in some degree the photographer's troubles. The machine is a Montgolfier, or fire balloon, which, as our readers know, ascends by reason of the hot and rarified air in the sphere, a heating arrangement in the balloon providing a supply of hot air during the whole of the voyage. The particular balloon under trial is the invention of M. Menier, who, by using a petroleum oil furnace, is enabled to inflate his balloon in half-an-hour. There is no necessity for a supply of coal gas, or hydrogen, which in war time is a difficult commodity to provide on the field, and moreover a much coarser and cheaper material can be made use of than ciled silk when hot air is employed instead of gas. Instead of darting into the air like an arrow, the Montgolfier balloon ascends with much deliberation, and never attains an height above three hundred yards or so, for it stands to reason, that as soon as the machine ascends to a stratum of air of the same rarity as that inside the sphere, there is an end to its buoyancy. A balloon such as this seems especially suited for military purposes, for it involves no special stores, and may be got ready within an hour; the height to which it ascends is quite sufficient for taking observations, and, being of a steadier and more stable character than the gas balloon, reconnoitring with the field glass or the camera could be undertaken with much less difficulty. Moreover it is less vulnerable, for a bullet, or even shell, tearing a rent in the canvas would have no such disastrous results as would be the case in a gas balloon. Before good photographs, however, can be taken at a great elevation, some modification will be necessary in the camera, to prevent the light from flooding into the instrument when an oblique view is secured; otherwise the result is an image that lacks sharpness and vigour.

*Glue for Mounting.*—Photographers are apt to be too

fastidious in their selection of a suitable glue for mounting, and sometimes go so far, even, as to employ pure gelatine in lieu thereof. The glue best adapted for mounting, whether employed alone or in admixture with gum, is, according to our experience, the ordinary "town-made" glue, which we prefer to "long Scotch," and other finer descriptions. One of the principal points is, to have a material which requires a minimum amount of water to render it adapted for mounting, and this is the ease when the gelatinous matter is worked up into a foam or froth; applied in this form to the back of a print, it is spread over the surface with great facility, and the small quantity of water in the material may be judged by the fact that when the tiny bubbles have subsided there is scarcely moisture enough to make it adherent. By having so little moisture, there is no chance of any liquid glue exuding from the margins of the print when this is pressed down, and, as everybody knows, there is nothing so untidy as a line of glue bordering the print. Bookbinders will tell you that it is only in the form of froth and foam that glue can be satisfactorily used for mounting, as it is then but sparingly applied, and may be managed in a cleanly manner. The finer sorts of glue and gelatine will not work into a froth so easily, and if applied in the form of a solution, a far larger quantity adheres to the back of the print, and then great care is necessary to prevent the excess which is pressed out from soiling the mount.

*A New Dictionary of Chemistry.*—Muspratt's Dictionary of Chemistry is to be re-issued by Messrs. Mackenzie, of Glasgow, for, during the past fifteen years, so much progress has been made in science that a large portion of the work is quite out of date. It will be almost entirely re-written, and the great improvements that have recently taken place in photography will not be overlooked. Mackenzie's Dictionary of Chemistry, as it will henceforth be called, may be looked for early next year.

### AMERICAN CORRESPONDENCE.

#### COLLODION FOR PORCELAIN PICTURES—THE DEVELOPMENT—SALTING PLAIN PAPER.

*Collodion for Porcelain Pictures.*—The last month seems to have had something in it which has made my correspondents very communicative. I guess it must have been the Chicago Convention. In lieu of anything special, then, I will give you a few notes from the letters I have received, beginning with a very excellent extract from Mr. G. Cramer, of St. Louis, on the much abused and little understood collodion for porcelain pictures. Mr. Cramer says:—

"The beautiful softness and richness of a good porcelain picture, which cannot be obtained in any other print, is so charming and so much admired by the public, that it is only surprising that porcelain pictures are not made more frequently. The public taste is in favour of them, so it seems to be on the photographer's side to introduce a greater demand for them than heretofore. The reason why they are not made more frequently seems to me in the trouble which most operators have experienced in the production of good, sharp, and brilliant prints on porcelain. They are less liable to fade than prints on albumen paper, and if glass of ordinary good quality is used, both for negative and print, they can be obtained sharp and distinct. But the principal reason for failure seems to lie in the instability of the chlor-silver collodion, which may work very fine when newly made, but after a short time will generally work flat and unsatisfactorily, because the chloride of silver is precipitated, and falls to the bottom of the bottle, instead of being kept in solution as it should be. As soon as the silver is precipitated the collodion is worthless for printing, and a new lot has to be made, causing considerable trouble and annoyance—too much, perhaps, for making only one picture at a time. It has been my aim to overcome this trouble, and I have succeeded perfectly in making two different collodions, one containing the silver, and the other the chloride, so that at a moment's notice a good working collodion can be obtained by mixing equal quantities from both bottles. Here are my formulæ,

which I have used to my best satisfaction for the last two years.

"*Collodion No. 1.*—First dissolve 60 grains negative guacotton in 2 ounces alcohol and 3 ounces ether. Take 120 grains nitrate of silver, powder it very finely, put this in a small bottle with 3 ounces alcohol, and heat by setting the bottle in boiling hot water until all the silver is dissolved in the alcohol. As soon as this is obtained, pour the silver solution, while still hot, in the collodion, stirring up all the time to secure a perfect solution.

"*Collodion No. 2.*—Thirty-two grains chloride of strontium, and 24 grains citric acid, are reduced to a fine powder and dissolve in 4 ounces alcohol; add 4 ounces ether and 30 grains negative guacotton. These two collodions will keep for any length of time, and when mixed in equal proportions will produce brilliant prints.

"To obtain fine porcelain prints proceed as follows: 1st. Coat the porcelain plate with albumen from fresh eggs and water, equal quantities. 2nd. After the plate has dried (without heat) warm it and let cool again. 3rd. Coat with the collodion (mixture of Nos. 1 and 2) in a moderately dark room, and dry the plate perfectly over a lamp. 4th. For printing, lay the negative on the prepared porcelain, being sure to have it in the right place; protect the back of the porcelain with yellow paper, and put plenty of patent clothes-pins all around the edges to secure a good contact. This is better than any porcelain printing-frame. 5th. In printing, put out in the light, at the same time, a silvered piece of albumen paper under a negative of the same intensity as that for the porcelain, and as soon as this paper print is dark enough, the porcelain picture is dark enough too. The negative should never be moved to inspect the proceeding of printing, which moving is unnecessary this way. 6th. After printing, wash first in plain water, next in water containing a very little salt. 7th. Tone in water 8 ounces, 1 drachm of gold solution (1 grain per ounce strong), made neutral by adding a drop of sal soda solution. 8th. After toning and washing, fix in hyposulphate of soda 1 ounce, and water 10 to 12 ounces."

Mr. E. D. Ormsby follows with some excellent suggestions on managing the development:—

"Many photographers devote too little attention to the developer. They have a certain formula for mixing it, and they always use it the same strength, be the subject light or dark, well timed under the light, or undertimed. We have a great power in the developer. As much depends on skilful development to obtain fine results in the negative, as skilful lighting—in fact, more, for by skilful manipulation a negative with faulty lighting can be made to produce good results. As an example, take children's pictures. Where you are obliged to light strong, and then can get often only two or three seconds' exposure, by using your ordinary strength of developer, and keeping your plate in motion during the development, you are bound to get harsh results. Increase the strength of your developer one-half, and hold your plate still during development, and note the difference in the result with the same lighting and exposure. For brunettes, light soft, time well, and use a strong developer, and don't rock the plate during development. For blondes, use a little stronger contrasts in lighting, time well, and use weaker developer, and keep the plate moving gently during development. For white draperies, use a soft light, long exposure, and a weak developer. The advantage to be derived by varying the strength of the developer, for different subjects and different conditions under which we are forced to work, is evident to all. But some will say it is too much trouble to keep several different strengths of developer on hand. I say, not at all. Make a stock solution of iron: 1½ ounces of iron to 20 ounces of water; acetic acid, 2 ounces. Keep a bottle handy containing water 20 ounces, acetic acid 2½ ounces, and use it to weaken your developer as you use it. By this method you can change the strength for each sitting if you wish."

Mr. W. L. Shoemaker sends the following useful suggestions in reference to salting plain paper:—

"To those preferring to salt plain paper for their own use, the following hints may be of use. The kind of salt employed has an effect upon the tint of the print; the weight of salt employed has the same effect upon the tint. Salting with a bath of neutral strength is shown by the print having a bluish, weak look, and an entire absence of purplish contrasts in the tints of the face. Over-salting produces paper that prints slow, blacks feeble and reddish, tone apt to be measly, and drying flat. Saxe plain paper—better floated than immersed, and should be laid on until the paper is perfectly flat, then lifted as carefully as in silvering.

The quantity of gelatine used in connection with the salting is generally different with every printer; but for medium Saxe paper I would recommend, at this season of the year, about one box Cox's gelatine to four gallons salt solution. In winter this can be nearly doubled. This same solution will be strong enough for the roll Saxe at this season. Salting with chloride of ammonium alone prints rather brownish, and the paper does not keep so well, or print as quick, as if used in equal proportion with common salt. So the résumé would be—

Chloride of ammonium	...	...	...	1½ grains
Common salt	...	...	...	1½ "
Water	...	...	...	1 ounce
Gelatine, 30 grains to quart for summer;				
double, or nearly so, in winter.				

Saxe paper so prepared should be floated and fumed same as albumen paper."

(To be continued.)

## BEGINNERS.

BY PROFESSOR H. VOGEL.\*

OLD and young, when they take up photography, have generally no ideal purpose in view beyond the practical project of gaining their daily bread with the aid of the camera. They care very little for the chemical reactions, or the action of the light, or the disposition of molecules, &c., and less still about the question whether photography is really an art or not; their object is to create a good business, and this goal they try to reach as quickly as possible. Generally speaking, they begin by undergoing a few weeks' tuition under some other photographer, where they learn to coat a plate in a passable manner.

I am often asked how long is really necessary in learning to become a photographer, and I always reply that the matter very much depends upon the individual himself. Those who possess a knowledge of chemistry, and have natural aptitude, will learn to take negatives in a very short time. I could mention a well-known scientific man who studied my manual carefully, and came into my studio impressed with a good deal of technical knowledge of the matter, therefore; and under these circumstances there was really nothing for him to learn beyond the practical manipulations, the pouring on of the collodion, developer, &c., and the adjustment and working of the apparatus, things obviously that can only be taught by demonstrations. This gentleman was qualified to operate in five days. Of course, during this short period he had not been looking on with his hands in his pockets, lounging about under the impression that he knew enough, but he practised at home what he learnt from day to day, and was exceedingly successful in what he did.

Another pupil that I had, who was an exceedingly good chemist, and thoroughly acquainted with the materials which he had to manipulate, turned out quite the reverse, for after six months' tuition he was still a clumsy operator. He belonged to that numerous class which are usually termed "Butterfingers." When he took up a plate to clean it, it slipped through his fingers; the dipper he would infallibly break after one or two experiments; the developer ran off the plate; and the filter never acted under any circumstances. I was exceedingly glad to get rid of so awkward a pupil, for I could never have made anything out of him. These two are, of course, merely instances, and do not hold good in all cases.

There are people who enter a studio without any previous knowledge, and who are exceedingly quick in picking up the first rudiments of the art. In a week they are so self-satisfied that they hasten home to follow up their success, but, unfortunately, find themselves stuck fast in a day or two over a question about which they possess no experience.

The matter is easily explained. It is easy enough, when you have good plates prepared for you, good collodion,

\* *Photographische Notizen.*

good dipping bath, good developers, intensifiers, &c., to secure a good picture, especially when found in a well regulated studio; success is here obtained without difficulty: but the beginner has to thank the pure chemicals and the photographer who has prepared the baths and solutions for it, for he does not know soon these may become changed after working or standing some time. He finds that the collodion—especially if the drainings go back into the bottle—becomes thicker and thicker; it gathers dust and impurities, and thus spots and stains are produced, whose presence he is unable to explain from his eight days' apprenticeship. It is the same with the dipping bath. Unfortunately, a bit of lime or kaolin has fallen into the solution, and this has rendered it slightly alkaline, and at once the plates show signs of fogging; or, again, the collodion is full of organic impurities, which produce streaks on the sensitive plate; or the film has other defects, such as pinholes, patches of insensitiveness, flatness, &c. All these phenomena, which may not come unexpectedly to those who have studied a photographic manual, are enough to confuse any beginner who relies upon his own brief experience in the matter. If to these well known defects we add, moreover, those that arise from faulty exposure or overexposure, bad fixing and varnishing, we have no inconsiderable host of disagreeables. I have pointed out in my manual as many as sixty different sources of failure, and this number is by no means complete. Those who desire to know something about these vexatious phenomena, and the means necessary for their avoidance, will not be able to finish their apprenticeship in a week, for it is only long practice and study that make the skilful photographer.

There are some people who work well enough under the guidance of another, but who are quite helpless if left to themselves. I have had pupils who, after six months' tuition, always come to me nervously with the question: "How long shall I expose?" These very seldom make good operators. Others, again, never come for advice at all, but at once set about preparing a second plate, in case the first has not been sufficiently exposed. These latter always learn something. I can mention others, again, who deemed the operation of plate polishing far too tedious, so they turned their attention to the matter of albumenizing the plates, but only experienced worse and worse failures. They employed one collodion after another, hoping in the end to find a way out of their difficulty, and never thinking for one moment that when strange materials are made use of some time must elapse before they can get thoroughly acquainted with their behaviour, for their employment may perhaps involve the application of chemicals other than those at hand.

Some little time ago I narrated an instance of an old and worthy photographer who could secure no results at all with a collodion which, in my hands, worked perfectly; and therefore a beginner may very well encounter such difficulties without being able to help himself at all. Of course the photographer in question was simply an operator, and had scarcely any knowledge of chemical principles, which are so necessary in employing collodion and dipping bath, to which it is the custom to ascribe most failures.

Dr. Jacobsen says that a little chemistry should belong to the culture of all men: and the photographer is a man. There are many operators who take excellent pictures, and yet boast that they know nothing of chemistry. This, however, is mere nonsense, for such people, if they have not studied chemistry theoretically, have been so long working with photographic chemicals and observing the reactions, that they have become possessed of the chemical properties of the things employed. They know from experience that iodide of ammonium when decomposed gives off iodine, and becomes red; that iodine colours collodion yellow, and starch blue; that nitrate of silver is easily dissolved in water, and in alcohol only with great difficulty; that it freezes at a high temperature, and becomes decom-

posed in one still higher; that it dissolves iodide of silver; that it is reduced by organic substances, &c.

In the building up of this practical knowledge piecemeal, of course many a pint of collodion is lost, many a costly silver bath thrown into the residue pan, and much valuable time frittered away in aimless experiments. The same amount of chemical knowledge they could have acquired in a tenth part of the time and tenth part of the cost by studying photographic chemistry; and this knowledge is readily acquired, for photographic chemistry occupies but a small section in the thick manuals on organic and inorganic chemistry.

#### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

11. I have not been able to trace any special connection between the chemical complexity of a substance and its diactinic power. Carbon in its pure form as diamond we regard as an element. In thin slices it transmits portions of the chemical rays of nearly all degrees of refrangibility, though none of the specimens which I examined exhibited any approach to the actinic limpidity of quartz. Phosphorus, on the other hand, though transparent to light in its melted condition, and equally regarded as elementary, appears to be nearly adiactinic, or impermeable to the chemical rays. In many cases the peculiar diactinic or adiactinic action of an element is traceable in its simpler chemical compounds. Thus the simpler combinations of sulphur, such as sulphuretted hydrogen, sulphurous acid gas, bisulphide of carbon, and chloride of sulphur, are all powerful actinic absorbers, while in the more complicated form of sulphuric acid and the sulphates of certain bases, the compounds are highly diactinic. On the other hand, the silicates are much less diactinic than silica in the form of quartz, or the bases which enter into the formation of the silicates; probably this may arise, as Professor Stokes suggests, from the difficulty of obtaining silicates, either natural or artificial, after fusion, perfectly free from iron.

12. No solid or liquid substance that I have as yet tried surpasses rock-crystal in permeability to the rays which excite chemical action. Ice (and water), as well as white fluor-spar, rival it; and pure rock salt approaches it very closely.† White topaz is a little inferior to the preceding bodies in diactinic capacity.

Amongst the various compounds submitted to examination, the fluorides rank first in diactinic power; then follow the chlorides of the metals of the alkaline earths. The bromides of the same metals appear to be less diactinic than the fluorides and chlorides, and this decline in power is still more marked in the case of the iodides. The short spectrum of these last-mentioned salts is interrupted by a well marked absorption-band at a point beyond H, represented on the arbitrary scale at 103.5, beyond which the spectrum is again faintly renewed to 113.5, and then it terminates abruptly. The cyanides appear to be considerably diactinic; but further experiments upon these salts, as well as upon the sulpho cyanides, are desirable. Sulphuric, carbonic, and boracic acids furnish salts with the alkalies and alkaline earths, which are also largely diactinic; the phosphates seem to be less so, and the arseniates still less. It is remarkable, that though the sulphates are so diactinic, the sulphites are considerably less so, and the hyposulphites are more opaque than the sulphites. The hydrates of the alkaline earths are also transparent. It is very difficult to obtain the alkaline hydrates perfectly pure; but a solution

\* Continued from page 459.

† A specimen of sea water which had been standing for some months in my laboratory, furnished a result identical with that obtained by using a strong solution of pure chloride of sodium.

of hydrate of soda and one of potash, obtained by precipitation of their respective sulphates with baryta, and concentrated in a silver dish, gave a very fair result in each case.

The diactinic capacity of the tartrates and citrates is less than that of the carbonates. That of the acetates appears to be about the same as that of the tartrates; but the results obtained with the acetates are somewhat uncertain, as it is difficult to procure these salts absolutely free from the empyreumatic products which accompany the acid as it is usually prepared. The oxalates have a low diactinic power.

But the group most remarkable for its absorptive action is formed by the nitrates. Nitric acid, whether dissolved in water or in combination with a metallic oxide, has a specific action in arresting the chemical rays; the less refrangible portion it transmits freely, and then intercepts the spectrum abruptly at the same point, whatever base be united with the acid, provided the base be capable of forming diactinic salts. The chlorates, on the contrary, are strongly diactinic.

13. From the observations above detailed, it appears that the following acids may be considered as possessing high diactinic capacity, viz.: the sulphuric, hydrochloric, hydrofluoric, chloric, carbonic, and boracic acids. Inferior to these are hydrobromic, phosphoric, arsenic, tartaric, citric, acetic and oxalic, hydriodic, sulphurous and hyposulphurous acids, whilst nitric acid is still less diactinic. Chromic acid arrests all the chemical rays; and the presence of a tinge of yellow or green colour in any compound is immediately apparent in a great reduction in the amount of its diactinic power.

14. Among the bases, potash, soda, ammonia, baryta, lime, strontia, magnesia, and alumina are eminently diactinic. Oxides of zinc, mercury, and lead, approach them in power; but coloured bases, like oxide of iron, nickel, cobalt, or copper, are very inferior; and when the salts which they form are green or yellow, they are nearly opaque.

It is remarkable that, notwithstanding the high diactinic quality of silica, none of the different varieties of glass transmit rays extending beyond one-fifth or one-sixth of the range afforded by quartz. This absorptive action is produced by a lamina of glass less than the one-hundredth of an inch in thickness, which cuts off the more refrangible rays almost as completely as a piece of glass of twenty times the thickness. All glass apparatus must therefore be abandoned in these experiments, and apparatus of quartz substituted for them.

15. I had no encouragement in my attempts to construct prisms of other materials than rock-crystal. Rock-salt offers no advantage, and it is too soft and deliquescent to yield prisms or lenses comparable with those of quartz. I did indeed make a considerable number of experiments with a hollow prism furnished with thin quartz sides, and filled with water. But the refractive power of water is less than that of rock-crystal, and its dispersive power is not higher. The addition of pure chloride of sodium till the water is saturated does not materially increase the refractive or dispersive power, whilst it appeared (in a very slight degree, it is true) to diminish the amount of the more refrangible rays; so that, on the whole, I found it more convenient to work with a quartz prism, the double refraction of which, in the position in which I used it, was so slight that it was not a source of any inaccuracy of importance.

(To be continued.)

## THE PRACTICAL PRINTER IN AMERICA X.

PRINTING-FRAMES, ETC.—(continued).

"Vignette Printing-Blocks.—In the making of the vignette printing-blocks, as well as in that of the printing-frames, great care should be given to the materials used. The

wood should be well seasoned, and the lighter it is the better; common pine or basswood answering very well for this purpose. The sizes of these blocks vary, of course, with the different sizes of the impressions on the negatives. For instance, blocks intended for 4-4 negatives should be in proportion to the size that 4-4 negatives are generally made.

"The opening of the wooden printing-blocks should then be in proportion with the impression on the negatives, as has before been said. Now for the 'whole size.' The width of the opening should be 3 to 4 inches, and the length should vary from 3½ to 4½ inches. For the next size, larger head, 7 by 9, the width should be from 3½ to 4½ inches, and the length from 4¼ to 5½ inches. For 11 by 14 vignette negatives the width should vary from 5¾ to 6¾, and the length from 6¾ to 8¾ inches. For 14 by 18 negatives the width should be from 6¾ to 7¾ inches, and the length from 9 to 11 inches.

"The above-stated dimensions answer only for a trifle lighter background than the average; for with a darker one a dark piece of paper would have to be placed at the sides; and if the draperies are dark, then there should also be a piece at the bottom part of the opening, for without it the block, and consequently the halo, would be too large. For a lighter background than the one for which I have given the above dimensions the block, if anything, would be a trifle small. It is impossible, however, to give a fixed rule for the size of the different vignette-blocks, because there are a very great many things to be taken into consideration which renders it almost impossible. The only way is to be guided by good taste. The depth of these vignette-blocks is probably about the most important part of the making of them. The importance of duly considering their depth may be readily seen and answered

by asking ourselves the following question:—What is the object of a deep vignette-block? We answer, To make the halos soft. These blocks should be deep in proportion to the size of the opening of the vignette of the block. Thus, for a 4-4 up to an 8 by 10 size vignette-block the depth should vary from about 1¼ to 2¼ inches. For 11 by 14 vignette-blocks, from 2½ to 3½ inches; and for 14 by 18 blocks, from 3½ to 4½ inches. This is, however, very changeable, according to a variety of circumstances. For instance:—

"1. The printing-frame may be so made that the vignette board, when tacked to it, would be very much raised, on account of the make of the printing-frame; then, of course, the block should not be quite so deep.

"2. The background of the negative may be very dark, or it may be very light. This refers more to the use of the board when printing than to the making of it; for the negatives should be made for vignetting, rather than the vignette-boards for the negatives; at least, this is so as regards the making allowance for the background of the negatives.

"3. The background may be faulty, so as not to admit of a large halo, but of a smaller, and as soft a one. In that

case we sometimes have to make special blocks, but often there are other blocks, of a different shape, which will, with the aid of one or two 'dodges,' answer very well. There are a number of cases in which the depth of the blocks for the same size negative should differ considerably.

"The shape of the opening of a vignette-block should be like unto that of an ordinary hen's egg. The narrow end represents the head or upper part of the block, and the wide end the lower part, because there should always be plenty of balance in a vignette, and that can only be obtained by having plenty of the body and a good share of the shoulders in the vignette. In the making of these blocks the opening should be bevelled out quite a distance towards the under part of the block, all of the way from two to four inches, according to the size, so that it will not stop the halo from printing out, and thus occasion a sharp line on the print.

"It is always an important item, in considering the making of wooden vignette-blocks, to have them as light in weight as possible, because, when the blocks are quite heavy, they are bungling to use, and their weight makes them dangerous to the safety of the negatives in more ways than one. The weight, then, of the vignette-blocks, especially those of the larger kinds, can be lessened by tacking thick pasteboard to the under part of the wooden block. In tacking this on, however, a part of the board around the under part of the whole block, and beyond where the bevelling of the opening stops, should be cut below the rest of the surface. The piece cut should be from a quarter to three-eighths of an inch wide, and a little deeper than the thickness of the pasteboard which is to be tacked to the block. The pasteboard should then be tacked to this under surface; and the heads of the tacks should be below the level of the real bottom of the block, so that there will be no danger of breaking the negative, on account of the tacks being pressed against the brittle glass on which the negative is made. By paying especial heed to this, it may be of great value to the young beginner, and will perhaps be the means of preventing his breaking more negatives in the future. Of course the advantage of so doing will be and has been recognised by all printers throughout the country. There is no danger whatever to the negative from breakage by the use of vignette-blocks made as has been described, and there is also no excuse for bad vignetting with blocks if the above is carried out.

"It will be seen by the perusal of the above that I have altogether omitted writing anything about a vignette-block smaller than a 'whole-size,' because, for those small sizes, I do not at all believe in using wooden vignette-blocks. Up to 4-4 size any way Waymouth's vignette papers are very superior."

## PROPORTION OF LIGHT AND SHADE.

BY R. J. CHUTE.\*

VERY many of the best photographic productions are defective in the composition of light and shade, producing either extremes of vigour by violent contrast of light and dark, or a sameness of middle tint over the whole that detracts from the value of the lights, and gives the picture an appearance of flatness.

This is a point that has evidently been overlooked, except by the most careful and cultured artists; the consequence has been that the relative proportion of light and shade in a picture has been a matter of chance or haphazard. Now, there are certain rules and conditions that govern this as well as any other department of art, and it is only necessary that they should be well understood, to be applied by the photographer to the works of art he may produce, as

well as by the old masters in the various schools of painting.

Sir Joshua Reynolds gives the following as the result of his observations "on the works of those artists who appear to have best understood the management of light and shade."

"Titian, Paul Veronese, and Tintoret, were among the first painters who reduced to a system what was before practised without any fixed principle, and consequently neglected occasionally.

"From the Venetian painters Rubens extracted his scheme of composition, which was soon understood and adopted by his countrymen, and extended even to the minor painters of familiar life in the Dutch school.

"When I was at Venice, the method I took to avail myself of their principles was this:—When I observed an extraordinary effect of light and shade in any picture, I took a leaf of my pocket-book, and darkened every part of it in the same gradation of light and shade as the picture, leaving the white paper untouched, to represent light, and this without any attention to the subject or to the drawing of the figures. A few trials of this kind will be sufficient to give the method of their conduct in the management of their lights. After a few experiments, I found the paper blotted nearly alike; their general practice appeared to be, to allow not above a quarter of the picture for the light, including in this portion both the principal and secondary lights; another quarter to be as dark as possible, and the remaining half kept in mezzotint or half shadow.

"Rubens appears to have admitted rather more light than a quarter, and Rembrandt much less, scarce an eighth. By this conduct, Rembrandt's light is extremely brilliant, but it costs too much; the rest of the picture is sacrificed to this one object. That light will certainly appear the brightest which is surrounded with the greatest quantity of shade, supposing equal skill in the artist."

How applicable and instructive are these observations to every photographic artist. As coming from one of the foremost portrait painters of his time, and being careful deductions from the works of some of the most celebrated artists, they are especially worthy of thought and application under the skylight.

The reference to the peculiar style of Rembrandt is more applicable to photographers of to day than to artists of any other period, from the fact that there are so many imitators of this style. "Rembrandt's light is extremely brilliant, but it costs too much." How true in reference to photography! How many brilliant lights we see that have but little value, because other parts have suffered so much in producing them. This method of lighting is an extreme that is only justifiable under certain conditions, or with certain subjects. For light drapery it is unquestionably preferable, as the larger portion is then thrown in the shade, and takes a subdued middle tint much more pleasing than the full glare of light; but for general practice the proportion of light used by the other masters will be more likely to lead to successful results.

The Chicago Exhibition showed that many of our photographers still strive for the "costly lights." The face, with its fine modelling, in most cases, is set in a great expanse of background of almost total blackness. The effect is not pleasing; the eye is soon wearied, and turns from it dissatisfied. A picture seen from such a distance that the details cannot be distinguished will attract attention at once, simply by the proper proportion and balance of light and shade, and, on coming nearer the eye, is captivated by its beauty, and dwells on it with satisfaction and delight.

It might be said that the Rembrandt style had cost too much in effort and failure; but, though the expense may have been great, yet the wonderful advance made in studying, comprehending, and producing light and shade will doubtless compensate for all the sacrifice.

## PHOTOGRAPHIC ENAMELS BY SWAN'S PROCESS.

A CURIOUS illustration of the tendency in persons of an inventive habit of mind to rush to the Patent Office to protect a discovery without first taking the precaution to ascertain whether the same idea had previously occurred to others, and whether any earlier discoverer had given publicity to such idea, has recently come under our notice. Very soon after the publication of Swan's Carbon Process, the very obvious suggestion was made in our pages that by the use of vitreous pigments instead of carbon in the tissue, photographic enamels suitable for burning-in on porcelain tablets would be obtained. Whether that method of producing enamels was tried at that time, we have no knowledge; but a few years ago Mr. William Firling, of Dorchester, sent us some good examples of photographs on porcelain, earthenware, and opal glass, all burnt in, which had been produced by this process, and we published his communication on the subject at the time. For some cause this method has not become popular, and has not, we believe, been extensively practised. A Parisian photographer, M. Paul Marny Godhard, has, however, had sufficient success, or sufficient faith, to induce him to go to what we fear will prove the bootless expense of a patent in this country for precisely the same process. His specification, recently published, runs as follows:—

"By this invention all kinds of drawings, portraits, ornaments, landscapes, and devices, can be obtained and reproduced or copied direct upon porcelain, delph-ware, biscuit, or enamel, and other materials of the same character, by the following means:—I take any kind of drawing, painting, engraving, or positive or negative pictures or subjects produced in the manner commonly practised by photographers according to the carbon process, and print or copy them in the manner practised by photographic artists. The proofs so copied on porcelain or other like materials I then coat or cover with enamel or vitreous glaze, and bake in an oven. And in this manner, and by this means, I obtain direct proofs of drawings, landscapes, and other devices or portraits on porcelain, delph, and other pottery wares.

"And in order to explain this invention more fully, I now proceed to describe the means by which it may be carried into practical effect.

"I take any drawing, landscape, and other device or portrait, and having produced a negative therefrom, I print from this negative the picture or portrait thereon

represented on paper prepared by means of the following bath:—

"First. A solution of glycerine water and colour.

"Second. Pure gelatine, melted in a water bath.

"Third. A solution of bichromate of potash.

"This bath is kept at a temperature of 90 to 100 degrees Fahrenheit. One surface of a sheet of paper is wetted in this bath, and then allowed to dry in a dark room.

"The negative plate on which the desired subject has been photographed is applied on the said prepared paper, and exposed to the light for a suitable space of time in the manner practised by photographers when copying ordinary photographs. When the paper has been sufficiently exposed to the light it is placed in cold water until well soaked. It is then applied on porcelain, delph-ware biscuit, enamel, or other materials of the same character and by means of pressure is made to adhere thereto. The whole is then placed in a warm water bath at about 100 degrees Fahrenheit. In the course of a few minutes the paper will detach itself, leaving the gelatine on the object on which it has been applied. Bichromate of potash having the property of rendering gelatine insoluble after it has been exposed to light, all the parts which have been exposed will be fixed to the porcelain or other material, and the remainder will be detached by the hot water, and thus leave a perfect picture of the negative on the object on which the said picture has been applied.

"I would here remark that mineral colours should be used in these reproductions, as vegetable colours would be destroyed by the heat. I then coat or cover the picture with enamel or vitreous glaze, and bake in an oven.

"Having now described and set forth the nature and object of this invention for 'An Improved Method of Producing and Reproducing Drawings, Devices, and Designs on Porcelain, Delph-ware, and such like Materials,' I would remark, in conclusion, that I hereby declare this invention to consist in, and I claim, the mode of reproducing drawings, devices, and designs on porcelain, delph-ware, and such like materials, substantially as above described and set forth, by means of the carbon process above mentioned."

## PORTRAITISTS' ADDRESSES TO THEIR CUSTOMERS.

CONTINUING our remarks upon this subject in our last, we next come to an American prospectus, which introduces the "Monumental City Palace of Photography" in Baltimore to the public, Mr. Richard Walzl being the proprietor. It is a handsome little pamphlet, arranged in dark green and gold, and it is distinguished by a mark of enterprise we have seen adopted in several similar American prospectuses, namely, a fine card portrait prettily mounted as frontispiece; and as the pamphlet is intended for gratuitous distribution, this picture must alone form a serious item in the cost. After some preliminary remarks addressed to the public, in which the proprietor states that, before building his "Photographic Art Palace," he made an extensive tour through the States and Canadas to visit all accessible studios, and so adopt the best points of all, he states that his aim has been to establish not simply a place where people may come only on business, but "to render his reception rooms cosy, homelike, cheerful, and comfortable, where visitors may find sufficient attractions to spend a few pleasant hours;" and visitors are emphatically informed that they "are always welcome, whether they desire to sit for pictures or not."

We have next an essay on photography, giving a sketch of its origin, rise, and progress, after which the pamphlet is chiefly devoted to points the entire silence on which we noted as a characteristic of Messrs. Robinson and Cherrill's pamphlet. Mr. Walzl does not omit to advise the sinner

most comprehensively on what he shrewdly styles "things you ought to know." First we have:—

*"When and How to Come.*—A clear day is not strictly necessary, as many suppose; on the contrary, a day when those light fleecy clouds are floating through the air is generally considered the most favourable. However, with the modern constructed sky-light which is found in our first-class establishments, any day except a very dark, cloudy, or stormy one will answer. When you intend to have your picture taken, do not come with only 'five minutes to spare,' or give your artist to understand you are 'in a great hurry.' It will not gratify him in the least, and it will not (in his estimation) be sufficient reason for him to slight some one else, but, like all others, you will have to wait until your turn comes. If you are on a visit, and desire to sit for a picture while in the place you may be visiting, do not wait until the day before you are to return to your home, but come when you have more time. If you come the next morning after being out nearly all night at a party or other similar places of entertainment, no matter how pleasant an expression you may assume for the occasion, tell-tale photography will let peep out in your photograph the fact that 'tired nature's sweet restorer' has been robbed. Remember the face is a mirror of the mind. Come when you are calm and in excellent spirits; come prepared to wait a few minutes cheerfully; and our word for it, the animated and pleasing expression which may thus be secured under such circumstances will be far better than a dozen re-sittings under any other. No matter how excellent the photography may be in all other respects, unless you come with perfect confidence in your artist's abilities, the expression will be unnatural, thereby destroying the chief beauty of the picture. Let as few of your friends accompany you as possible, as a crowd only results in confusion, and often makes it impossible for the artist to secure a satisfactory picture. When convenient, it is preferable to examine specimens, and select such styles as you desire, a day or so before sitting. When this is done, you will, if promptly on time, avoid being delayed."

Some judicious hints follow on the very important point—

*"How to Dress.*—When anything more than a vignette picture is desired, it is very essential that a suitable selection from your wardrobe is made of such drapery and wrappings as will be as much as possible in characteristic keeping with the style of a picture to be taken. Dressing the hair in an unusual style, simply because you are to have your picture taken, is generally sure not to please you when you see your picture. When you are aware 'how' ribbons of different colours photograph, the folly of wearing such as will take white, or very light, in dressing or arranging the hair, will be readily understood. A single flower, or a small spray of them, arranged with taste, is always more effective than ribbons. It is not always expedient to follow the fashionable mode of dressing the hair by all ladies who intend to have their photographs taken, for the emphatic reason that photographs are sometimes 'horribly correct.' Ladies with broad faces should have the hair arranged as much as possible on top of the head; while those of angular faces should always manage to dress their hair on the side with 'puffs,' frizzes, or curls. If the neck is deemed too long, a few graceful drooping curls may be so artistically arranged as to completely overcome the objection or fault. Never use too many curls, for in a picture it causes the head to appear entirely out of proportion to the body (which is really the case).

"Avoid, when arranging the hair, all abrupt angles; they appear very ungraceful in a picture. The materials with which the most graceful drapery may be secured, and which appear very rich in the photograph, are silks, satins, reps, silk poplins, moire antiques, &c. Pale pink, light blue, lilac, lavender, and light purple colours always

photograph very light; but such colours may be worn to advantage when pictures are desired with a dark background. The following colours in the photograph come out a very pretty shade of light grey, and can be so artistically managed as to excellently harmonize with most any complexion:—Navy blue, fawn, dove, crimson, rose, pink, light green, plum, dark purple, and magenta. The following colours photograph quite dark, and appear very rich in the picture:—Light brown, orange, yellow, claret, scarlet, dark buff, and leather colours. The colours which take still darker and nearly black are the dark green, cherry, browns, dark orange, wine, and golden brown colours. Nothing photographs better than heavy black silk. Lace work of all descriptions can always be introduced with most pleasing effects. Avoid all white drapery of an opaque nature. The only white drapery of which good photographs may be secured are such goods as Swiss muslin, tulle, &c. With such a black lace shawl may be used very effectively. Always avoid prominent striped or plaid goods, which do not yield pleasing pictures. Black velvet is not suitable for persons of light complexion. Blondes should dress in something lighter than brunettes. Jewellery is not recommended only to a slight extent. Long gold chains generally come out sufficiently light to make an unartistic contrast.

"Never powder the face unless the artist directs or advises it. People often wonder how it is that actresses, as a general rule, always make excellent pictures. It is an erroneous supposition to attribute this to their superior natural attractions. When they come it is with a purpose. They always bring with them a selection of toilet requisites, which they give the artist permission to judge of which produces the most artistic harmony in the picture. They are calm, self-possessed, and have full confidence that the artist is competent.

*"Gentlemen's Dress.*—As a general rule, black is preferable, although it in many instances somewhat depends upon the style of picture desired. The gentlemen may glean some useful information as to how their 'stunners' necktie and scarfs will photograph by reading the remarks on how the different colours photograph. If you wet or oil the hair too much, it will make a gloss on it that will appear white in the picture. Dress the hair as loose as possible; do not comb it down too smooth."

The next subject, the position of the sitter, belongs more to the artist than to his customer; but some good hints are given to the latter, who is advised to be tractable and obedient.

*"Position.*—This is one of the very important stages of the operation. Here the artist's true ability and knowledge of art are thoroughly tested. For the sitters to dictate and tell the artist how to 'fix' them, is virtually declaring him *not* to be an artist, and exhibits the fact that no confidence is had in the artist's merits. A moment's consideration on the part of the sitters, and they must certainly be aware of the utter absurdity and unwise course of such procedure. It is the artist who takes the picture, and his practised eye can more readily and truthfully determine which may be the most favourable position; and it is certainly just as much to his interest to secure an artistic picture of you as you are anxious to get one. While, in comparison, you have nothing at stake, he has his reputation as an artist, and, if not interfered with, will always maintain it. The head-rest is strictly necessary; no matter how certain you are that you do not need it, it is impossible to make good photographs without it is used. The pulsations of the heart are sufficient to move the head (if the rest is not in use) enough to destroy the pleasing and artistic effect of the picture. Please do not, when the artist has, after no title study, arranged you in a position to suit his taste, move or change about, and thereby spoil it. Avoid, just about the time the exposure is to commence, the unnecessary evil of giving yourself any 'finishing touches to your

collar, your curls, or, in fact, anything, for perhaps the least movement of the kind will destroy the position entirely, which will necessitate the accomplishment of the work again, and in the second trial under such circumstances, neither the artist nor the sitter feel the same degree of interest in the result. The artist becomes embarrassed at your lack of confidence."

On the subject of expression some good remarks follow, and the sitter is urged to avoid all effort and anxiety about the portrait. Mr. Walz says:—

"*Expression.*—This is the all-important event to insure success. Expression is the life of the picture—the likeness in its unassumed and most correct form. When this is therefore understood, the sitter can appreciate the importance and necessity of coming in a cheerful and happy mood. It is impossible for the artist to coax out in the picture an expression that was not on the face of the sitter. If the sitters be tired and worried in mind, no matter how 'nice' they may look when sitting, it will plainly be seen in the photograph that the mind is portrayed in the face. The proper way is to feel perfectly natural. Do not try to be anything but yourself. Avoid, when sitting, this unnatural way that many have of looking with all your might. If you are thinking about how you look, and are 'so afraid it won't be good,' you can rest assured there will be anxiety pictured in your face when you see the proof. The proper way is to sit down in a cheerful mood, letting the mind dwell on some pleasant theme—something that will bring your whole-souled nature out in your expression. Keep the eyes steady on the object as directed, winking as under ordinary circumstances. Do not strain the eyes in the least; it is not necessary. It has been our aim to have the appointments and surroundings of our rooms of such a character as to engender pleasing thoughts, and help the sitter to feel at home, by which means the artist is greatly assisted in securing that easy, natural, characteristic expression, which it is his great pride to reproduce."

A capital idea follows, which may be worth adopting by many. One day in the week is set aside for taking children. Every photographer knows how sadly the business of the day is interrupted by the necessity of taking one or more children whilst other customers are waiting; but also knows that it is important not to refuse taking children if the patronage of their parents be worth retaining. Here is the solution of the difficulty:—

"*The Children's Day—Saturday.*—After careful consideration, we conclude, for the mutual good of all parties, that it is best to have a special day in each week for taking children's portraits, when special pains and attention will be devoted to them. Generally adult patrons dislike to be kept waiting by children, who, in many instances, have a faculty of not sitting still; and the time occupied in trying to secure their picture causes the artist to lose customers, when in many instances he fails to secure a picture of the restless little one, and consequently, after having lost a paying customer, has in the case of the little one his labour for his pains. It will be much more pleasant and agreeable, therefore, to have a definite understanding. The little ones on their day will be delayed but a short time, when perhaps, on any other day, before their turn would come, they would get restless, tired out, and sleepy. It will be understood, however, that the 'little ones' referred to means children under five years of age; all over that age can come at any time.

"Young children should always be dressed in white or very light coloured goods, and in all cases should be brought to the artist's rooms before noon. In this age of civilization it is not now deemed necessary that the infant prodigy should be, relatively speaking, accompanied by its parents, grandmother, and relations generally. The mother and nurse are, now-a-days, supposed to be sufficient for the occasion. The artist has more experience in

taking pictures of babies than you have, so it is best to let him take the picture. If the youngster's picture is not secure after two trials, the artist can judge whether it is best to renew the trial, or to come again another time. Do not attempt to force the child to sit when it is determined not to. It is a mistaken idea to allow the children to have 'sweet things,' or to give them toys to hold, as both attract their attention, and are therefore only a hindrance instead of an assistance. Please be reasonable, and do not expect impossibilities in children's pictures. It is impossible to make a standing picture of a child that cannot walk, or of one under five years of age. If it were possible, it would not be natural nor childlike. Better always let the artist arrange the child properly. Groups of children under five years of age cannot be satisfactorily made. In photographing infants, the face is what the artist strives to reproduce; and as, on account of the peculiar restlessness generally exhibited, the time of exposure is much shortened, therefore it is impossible to show the hands and feet as perfect as though they were kept still. At all times, however, the best that can possibly be accomplished will be cheerfully done. It is impossible to secure a picture of a sick child. Children should be brought on bright, clear days only."

A series of short chapters on miscellaneous points follow, the first making the stern announcement that "photographs must be paid for when ordered." This is a very debatable matter. Some photographers insist on the wisdom and convenience of entering in a book details of order as soon as a style has been selected, and a receipt made out as the unmistakable hint that the cash must then be paid. Others prefer to take the order after the sitter has seen and is well pleased with the portrait. Here are Mr. Walz's remarks on this subject:—

"*Photographs must be Paid for when Ordered.*—This is an established rule and custom prevalent among all leading establishments. It is done to shield the artist from imposition by those who are impulsive (?), such as sit for their pictures when in a certain mood, just for fun, and, if they are not paid for, never call for them. This is no fun to the artist. Another class insist on seeing the negative: it may be a very excellent one; but they, not being capable of judging from the negative, will not believe the artist, but deem their judgment more wise than his, and think to themselves, 'Well, as long as it is not paid for, I won't call for it.' Others can see, therefore, the necessity of this rule, and may also understand, because it is necessary to comply with the rules of the establishment, that their honour is not the least questioned. On large photographs and large coloured work, in amount of \$25 and over, it will only be necessary to advance one-half the price of the work, and the balance, cash on delivery. A proof will be made and shown when desired. In no case will we allow an inferior picture to leave the establishment.

"Please do not hurry us in the finishing of your pictures. They will be finished just as rapidly as it is possible for them to be, in a manner consistent with the production of artistic results. It generally requires from five to seven days, and in cloudy weather a day or two longer. All can be finished as well as a few at the same time, therefore do not expect 'some of them a little sooner.'

"Positively no duplicate prints will be delivered, from any negative, to any parties but the sitter, unless we have verbal or written consent from the proper authority to do so.

"No prints will be used for specimens without permission. All imperfect prints, or any printed over the original order, are always destroyed.

"Please preserve your check for future reference, and, in ordering duplicates, the number of the check is all that is required to give us."

In the chapters which follow, the various kinds of work done are detailed, and frames, albums, and other goods

described. Curiously enough, no list of prices is given, although repeated allusion to the prices is made. The pamphlet closes with a few specially emphasised paragraphs as to the rules of the establishment, one being that the clergy will be furnished with plain photographs at half the price charged to the ordinary public, and that no sittings will, under any circumstances, be made on Sundays—an announcement which, we should hope, it would not, as a rule, be necessary to publish.

#### FRENCH CORRESPONDENCE.

M. LE COMTE LUDOVICO DE COURTEN has just forwarded me an interesting communication, which I have much pleasure in making known to your readers, for while the letter contains information more particularly interesting to photo-lithographers, it nevertheless treats of matters which will be useful to all.

When engaged upon the reproduction of engravings—or, to be more precise, of line drawings—it is often found that two difficulties present themselves; either there is too much transparency in the cliché, or there is a foggy appearance, more or less marked, over the whole plate. The first defect is due to a pose which has been too short (that is to say, the light has not acted sufficiently upon the collodion plate); the second defect comes from intensifying the plate too much: both, of course, have an injurious action upon the result.

M. de Courten says that works hitherto published give but very vague directions upon the subject, and often erroneous ones. He thinks that as every day the processes of printing with greasy ink will become more and more vulgarised, operators will be only too glad to be informed how they may be able to secure a clear and transparent cliché with a ground sufficiently opaque to secure a transfer upon stone.

M. de Courten has taken up the two processes indicated by M. Geymet, and it is by means of the first, modified in a very happy manner, that he has been enabled to obtain a very successful result. He rejects altogether the employment of hydrosulphate of ammonia, whose violent and irregular action has almost always the effect of spoiling the best plates; besides, it has an injurious action by volatilizing, and thus damaging other preparations in the laboratory.

My ingenious correspondent thus proceeds: he prepares two solutions as follows:—

No. 1.—Alcohol ... .. 5 cubic cents.  
Bichloride of mercury ... 2 grammes

The bichloride of mercury is, in the first place, finely powdered, then the alcohol is added, and, after the solution is pretty well complete, there is added one hundred cubic centimetres of water.

No. 2.—Iodide of cadmium... .. 2 grammes  
Water ... .. 100 cubic cents.

The first solution may be employed in the form of a bath; the second is poured from a lipped glass.

The cliché, having been developed by means of sulphate of iron and well washed, presents an iodide film of a most limpid character in the lines, and is then fixed in a five-and-twenty per cent. hyposulphite of soda bath. Sometimes the negative appears so weak that one feels tempted to reject it as unserviceable; but this weakness is of little importance. Nevertheless, if deemed necessary, after having withdrawn the cliché from the soda bath and washed it thoroughly, it may be intensified by pouring over it some more of the solution of iron which has served for development, adding a few drops of silver to it previously. It is sufficient if the film has obtained a slight increase in intensity. This small addition of silver aids considerably the precipitation of the mercury.

According to M. de Courten the employment of pyrogallie acid should be rejected, for its action takes place

principally upon the transparent portions; these become covered with a precipitate which injures the cliché beyond all remedy. In any case, before the cliché is plunged into the bichloride solution the plate must be freed from every soluble reagent, and well drained. It is immersed face upwards, and the bath is shaken so that the solution covers the film in wave-like motions.

The operator has a certain latitude for intensifying. With a rapid action he obtains a dark grey, and afterwards a black, precipitate, very agreeable to the eye; if the immersion is longer, then the film becomes of a whitish-grey, and the cliché has, subsequently, a yellow ground, which is very impermeable to the light. M. Courten, however, says that the lines are sometimes covered with the precipitate in this case.

On the exit of the plate from the bichloride solution it is washed with extreme care, and then intensified by covering it with a solution of iodide of cadmium, which is applied several times. Almost immediately the film, viewed by reflection, assumes a yellowish-white tint, and the lines have an extraordinary transparency. Seen by transmitted light, the ground is opaque and of a velvet aspect.

The essential condition of success is for all the bichloride of mercury to be converted into proto-iodide of mercury; this change is effected when the back of the negative, seen by reflection, presents a uniform green tint, without any trace of grey. M. de Courten insists upon this point, which he states to be of the highest importance.

The operation ends with a thorough washing in plenty of water, which one need not fear to prolong; afterwards the plate is covered with a solution of gum made up of:—

Gum arabic ... .. 12 grammes  
Water ... .. 100 cubic cents.

M. de Courten has tried the iodide of potassium, which M. Geymet recommends in his manual, but he has found iodide of cadmium preferable. Iodide of potassium gives less intensity, and moreover it gives an unequal film with yellow streaks. This is a grave defect, which is not met with when iodide of cadmium is employed, which forms, no doubt, a more stable metallic compound.

The cost of iodide of cadmium is higher than that of iodide of potassium, but M. de Courten thinks this of secondary importance in face of more successful results. My correspondent ends his interesting communication in calling to mind the fact, that in the event of poisoning by means of bichloride of mercury, the best antidotes are white of egg, which combines with the mercurial salt, and forms an insoluble compound; and proto-sulphate of iron diluted with water, which forms, with bichloride of mercury, bisulphide of mercury and proto-chloride of iron, which have no injurious action upon the human organization.

A civil engineer, M. Van Tenard, has designed, and intends to bring out commercially, an enlarging apparatus suitable both for painters and photographers; it is, in fact, an instrument for securing enlargement of opaque objects.

A simple earte-de-visite placed in the apparatus is reproduced most accurately upon a screen placed parallel to the image, according as the screen is made more near or distant. The light of an ordinary oil lamp suffices for the production of a perfectly clear image.

To secure a photograph upon glass or paper, it is sufficient to replace the screen either by a sensitive plate, or a sheet of paper prepared with iodide of silver. Without in any way disarranging the disposition of the apparatus, the ordinary lamp may be replaced by a magnesium lamp, and by means of this photogenic light a reproduction of the size of nature may be secured.

In the same way, ordinary photographic clichés may be enlarged. A painter would probably be content with an enlarged image thrown upon the screen, from which he might make his sketch, either in crayon or chalk, to form a basis for a painting.

Electric or oxyhydrogen light may also be applied

in this instrument. M. Hermann, one of our most distinguished photographic portraitists, who has promised to bring the apparatus to the notice of the public, has announced that he will give daily demonstrations with the instrument in his studio. I propose paying him a visit, and will give an account of my experience in one of my next letters, and describe the practical details of the instrument.

At the last meeting of the Photographic Society of Marseilles, a member having asked whether silver prints fixed by means of sulphocyanide of potassium instead of hyposulphite of soda could rival in permanency photographs produced in carbon or fatty ink, M. Leon Vidal replied to the question by referring to a very simple experiment; it is sufficient to plunge the point of a needle into water feebly acidified with nitric, muriatic, or sulphuric acid, and to prick the carbon and sulphocyanide prints, when there is formed on the latter a white spot, while the former will remain intact. It is evident, therefore, that photographs with a metallic basis are subject to alterations which result from the modifiable conditions under which they are produced. The moisture of the air, the traces of carbon, sulphur, and alkaline or acid matter, that they contain, and the action even of the mounting material employed, are all prone to bring about an oxidation of the prints, thus leading to their destruction. All such causes of change are, however, without effect upon pigment prints.

BY GEORGE CROUGHTON.

##### ABOUT PRINTING.

Mr. HEARN (the "Practical Printer in America") recommends drying the sensitive paper quickly; and a correspondent asks, in your page of "Notes and Queries," if this is in accordance with the experience of photographers in this country. I, for one, cannot agree with him in this respect, having found it impossible to get the paper to lie upon the negative without wrinkles, which no amount of pressure could flatten. I am daily using whole sheets of albumenized paper for enlargements, and can speak from experience, that unless the paper is allowed to dry spontaneously, it will wrinkle or cockle, and will not come into perfect contact with the negative.

The experience of English photographers is also asked, in the same page, as to the advantage of fuming the paper. When there is so much good testimony in its favour, it is with some diffidence that I state my experience of its effects. I have found great uncertainty in its use; sometimes it would appear to produce prints with greater brilliancy after toning, but they have invariably taken a turn for the worse in the hypo fixing bath; at another they have been stained by unequal action of the toning. It may be that the bath I use does not agree with the fuming, and as I can get as brilliant prints with this toning bath as any of the fumed prints I have seen, I do not see the advantage of the extra trouble. The formula for making the toning bath I use has been frequently published, but without proper directions for use. It is the most economical bath I know or have heard of, as I can tone four sheets of paper with one grain of gold. As a good and reliable toning bath is a desideratum, I append the formula and working directions. Break a fifteen-grain tube of chloride of gold in a two-ounce bottle of distilled water; add to it fifteen grains of chloride of lime. Every drachm of this will of course contain somewhat less than a grain of chloride of gold. If I have four sheets of paper to tone, I take one drachm of this and put it into a pint jug with a pinch of precipitated chalk, and then fill up with boiling water. It is a point of great importance that the water should be boiling when poured upon the solution of gold and lime. When cold, this is ready for use.

Now comes the most important part of the whole

proceedings: *put your prints into the toning without any preliminary washing whatever.* Do not over-tone, stop just short of the tone you want, and transfer to a dish of water made just salt to the taste with common salt; this prevents the toning being continued, as it would be without the salt. When all are toned (and it tones very quickly), give the prints fresh water (without salt), and transfer to the usual hypo fixing (I use one pound to two quarts of water). The advantages I find in the use of this toning are brilliant purple shades with a warm flesh like tint; in the middle tints it preserves the most delicate demi-tints of the picture, and saves both trouble and waste, as all the chloride of silver is saved in the toning, so that you have all saved in a pint instead of having to keep two or three washing waters. I have used it for something like ten years, and shall never use any other.

The subject of washing prints after the hypo is one on which great difference of opinion is expressed. My experience is in favour of short washing, but with thorough changes of water. I wash my large prints (19 by 14) in flat wood trays three inches deep, twenty-four inches long, by eighteen inches wide. I have three of these, and the prints are transferred from the hypo, after thorough draining, to one of these, which has been filled with water, and left for about five minutes. I have two canvases upon frames, bought at an artist's colourman's, prepared for painting upon. One is put under a tap, so that the water falls upon the centre. Upon this the prints are placed one at a time, with the water running upon them, and well sponged back and front, and placed upon the second canvas (which is standing on end) to drain. They drain thoroughly, and are then transferred to tray No. 2, which is filled with clean water, and let remain for the same length of time as in No. 1, and then the spouging and washing under the tap are repeated. When that has been done four times, I am quite confident all the hypo that can be got out is out of them, and they are blotted and mounted right away, for I do not believe in long soaking, which takes all the brilliancy out of the pictures, and rots the sizing.

I suppose Mr. Hearn has several chapters to come upon printing dodges, for it is there that English printers fail as a rule. There are, of course, exceptions, but, as a rule, printers take very little interest in producing the best possible results from the negatives given them to print. "If the negative will not produce a good result by simply putting the sensitized paper upon it and keeping it out in the light till it is printed dark enough, it is the fault of the operator, and no business of his." This is the argument of the average printer. But the printer who takes an artistic interest in his work is up to every dodge to improve upon indifferent negatives: tinting his paper before putting it upon a hard negative; covering a too soft one with matt varnish or tracing paper, and increasing the brilliancy of the resulting print by thickening upon the lights with pencil or colour, and clearing out the shadows by scraping away the varnish or gumming the tracing paper; cutting masks, and covering up some parts while others darken; and the thousand and one little dodges that suggest themselves to an intelligent and educated taste. "Ah! but," said a friend, "where will you find a printer paid to take all that trouble and interest in his work? When you can get the masters themselves to appreciate such work, and encourage a printer in it, you may hope to see more of it done; but, as a rule, printers are miserably under paid. Where do you find a printer getting the same salary as an operator? Yet he ought to be the equal of the operator in artistic taste and judgment, to be able in the printing to correct his faults or shortcomings, and therefore he ought, in common justice, to be on an equality with him, in both position in the establishment and in regard to salary; but while masters think that any boy or girl will do for printing, you will not find a man with any pretension to artistic taste or skill remain in the position of printer." I am afraid my friend is right.

### PHOTO-TYPE PRINTING.

SIR,—In your last issue you say, with much truth, that it is "singular that in this country, where so many clever mechanical methods have originated, photo-type printing is comparatively unknown." Much of this is possibly owing to the "patent bogie," many ingenious persons not caring to run the risk of the trouble and annoyance of a controversy, or, worse still, a law bill. If the small printing presses to be used with type, and printing the size of small note paper, have been found to answer so well, possibly some one with time and opportunity for experiment might hit on a plan for small *litho* presses, for small subjects in line; or an arrangement for small gelatine blocks. All this would be of service to many engaged in the arts, in schools, &c., &c., as well as to photographers in general.—  
Yours, &c.,  
OBSERVER.

## Proceedings of Societies.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE last outdoor meeting of the season was held last week, when the members, taking advantage of the newly opened branch line to Balerno, proceeded to Collinton, and wrought their way up to Curry.

There is no city with which we are acquainted that contains within a circle of ten miles so much food for the camera; and the construction of this railway has opened up one more exceedingly beautiful locality. The new line branches off the Caledonian a little beyond Slateford, and after crossing the Edinburgh and Glasgow Canal, runs close by the water of Leith, which it crosses and re-crosses nearly a score of times, through a continuation of most picturesque and varied bits of landscape, including numerous waterfalls, fine bridges—both old and new—quaint old mills, with their sleepy-looking cauld, reflecting in all its beauty the autumn-tinted foliage which gives such a charm to the tree-clad country at the present time; and last—not least—many of the cosy-looking cottages, now so fast disappearing from the scene. We would advise those who intend to visit and photograph the beautiful glen, to go by rail to Balerno, and then walk back along the line; and can assure them that if they get a favourable day, and have a couple of dozen reliable dry plates, they may easily bring home a couple of dozen of really excellent pictures. In connection with the excursion, the two secretaries, along with two friends, proceeded on a prospecting trip on the previous Tuesday; and, acting on their advice, the party came off at Collinton, intending to work their way up to Curry. The first picture lay at the opposite end of the tunnel, which is close to the station, and through which they had just passed; but the obliging station-master not only gave the necessary permission, but kindly furnished them with a lamp to guide their footsteps along the somewhat uneven path.

On emerging from the darkness of the tunnel, the view which confronted them was really grand—a miniature Killiecrankie, in fact—possessing the advantage of being easily included in one picture, and consisting of two finely foliage-covered hills, the various tints of which were admirably rendered by unclouded sunshine, and undisturbed by a breath of wind; while through the valley ran—or rather tumbled—the river in numerous little falls, the white spray from which glittered in the light like diamonds. Here the cameras were unpacked, and in a short time all were at work. In consequence of many of the members being out of town, there were less than the usual number present, but it was noticed as a somewhat unusual fact that everyone present had a camera, and also that all the plates were by the beer and albumen modification.

Although the light was good, there was one side of the valley in shade, and in consequence rather long exposures were given; they ranged, in fact, from ten to thirty seconds. The next halt was made at a point immediately in front of the station, where there was an old willow-tree overhanging a deep pool, which, with its surroundings, formed too great a temptation to be passed without an attempt to transfer it to the collodion film. This was accordingly done, and again the party were on the move.

In this way the journey to Curry was made, amidst such fun and enjoyment as we believe can only be realized by votaries of

the camera. By the time Curry was reached the sun had gone down, but there were two pictures they were all anxious to get, a group of rose-clad cottages with thatched roofs, and a fine combination of an old tower, a bridge, and a ruined cottage. The former got forty minutes, and the latter a whole hour, in consequence of the badness of the light.

The cameras were then put up, and an adjournment to the hotel made, where Mrs. Mackenzie had ready the usual wind-up—a tea dinner—to which, of course, full justice was done.

After removal of the cloth, the chair was (in the absence of the president) taken by Dr. John Nicol, and the usual formal business was transacted, by which time the return was due, and the party started on the homeward journey, showering blessings on the head of the Caledonian Railway Company for opening up such a rich field of glorious work for the laudscapist, and resolving to return to the ground at the earliest opportunity. We may add, that out of the whole day's work, there were only three failures.

## Talk in the Studio.

A COPYRIGHT QUESTION.—Mrs. De la Rue, art dealer, 30, Museum Street, Bloomsbury, was summoned before Mr. Vaughan for infringing the copyright of Mr. Arthur Lucas, the well-known photographer, in a certain photograph entitled "On the Track." Mr. George Lewis, jun., appeared for the complainant, and Mr. J. L. Longstaffe appeared for the defendant. It appeared that the picture in question is one painted by Mr. Henry Benjamin Roberts, the member of the Institute of Painters in Water Colours in Pall Mall. The copyright of the picture was sold to Mr. Lucas, and he has since registered it. Some photographs taken by him of the picture have been published. From an advertisement it was discovered that the defendant was selling some scrap-photos, entitled "On the Track." One of them was bought, and it proved to be a photograph of a bad copy from Mr. Roberts' picture. Mr. Lewis called Mr. Roberts, who said that he had painted the picture for the Royal Academy. It was there exhibited on the "line," and was much admired by all. He sold the copyright to Mr. Lucas. These photographs which had been sold by the defendant were evidently photographs of a very bad copy of his picture. They were calculated to do him very great injury. Cross-examined by Mr. Longstaffe: He did not copy his picture from any French artist's painting. It was drawn from real models, and the dresses and arms had been lent him from a club of which he was a member. Mr. Longstaffe, for the defendant, said that after this evidence he had made an arrangement with Mr. Lewis, by which the summons would be withdrawn. His client had bought a picture in France as original. She believed it to have been painted by a man named Le Brun. The picture had been photographed, and she had sold copies for some months now in the firm belief that the picture she bought in Paris was original, and that there was no other like it in the world. After what Mr. Roberts said, however, it was evident that it must have been a copy she bought in Paris, and she was therefore quite ready to give up the negative, and promise not to sell any more of the copies. Mr. Vaughan said this was no doubt the honourable course to take. The copies sold by Mrs. De la Rue were evidently calculated to do Mr. Roberts an injury, as they were copies of a very inferior picture to that of Mr. Roberts. In the event of the negative being given up the summons might be withdrawn.

MR. LOUIS SEEBORN, one of the chief photographers who embarked on the *Swatara* in June last as a member of the American transit of Venus expedition, died at Bahia on July 22. He had been extremely ill during the voyage, and was ordered home by the medical officer of the vessel, but died of fever before he could be removed.—*Nature*.

THE APPROACHING TRANSIT OF VENUS.—The scientific journals and the members of learned bodies are at present very much engaged in considering matters connected with the transit of Venus over the sun, which will take place on Tuesday the 9th of December next, and for the observation of which her Majesty's Government have voted a sum of £25,000, supplemented by grants from the governments of France, Germany, Russia, and the United States. There will be many stations for observation, those for the English observers probably being the island of Woahoo, off the East Coast of Australia, Kerguelen's

Island, and Rodriguez Island, in the South Indian Ocean, at Auckland, New Zealand, and at Alexandria. It is thought that Russia will occupy about thirty stations, while France, Germany, and the United States will furnish about twelve each. It appears that the observation of the transit of 1769 was due principally to Dr. Halley, who first suggested this mode of computing the distance of the sun from the earth in 1716. The transit of Venus, which will occur on the 9th of December, will not be visible in this country; but it will be distinctly seen in New Zealand, Australia, the East Indian Archipelago, and various parts of Southern Asia. It appears that the transit of Venus which was observed by Captain Cook's expedition at Otaheite in 1769 led to the calculation that the distance of the sun from the earth was 95,300,000 miles. It has since been considered—better astronomical instruments having come into use—that the distance is 91,750,000. The next transit of Venus (after that of 1874) will be on December 6th, 1882, and as follows:—June 7, 2004; June 5, 2012; December 10, 2117; December 8, 2125; June 11, 2217; June 8, 2255; December 12, 2360; December 10, 2368. In reference to Lord Lindsay's expedition to the Mauritius, to which we referred last week, the Earl of Crawford writes as follows to *The Times*:—"I have just read in a leading article of *The Times* of last Wednesday a very flattering reference to the expedition to the Mauritius. It is my son, Lord Lindsay, who has organized this expedition and undertaken its duties personally, his devotion to science, and to astronomy in particular, being as determined as my own has been to letters. He is now on his way to the Mauritius, *via* the Cape of Good Hope, but his able assistant, Mr. David Gill, has already arrived there *via* Aden, and is making the preliminary arrangements for the arrival of the instruments, which Lord Lindsay is taking out in his yacht. Mr. Gill has received most efficient and kind assistance from the Surveyor-General, from Mr. Meldrum, of the Observatory, and especially from M. de Chasales, a venerable French gentleman, one of the old proprietors, who lives in a sort of patriarchal state in the north-east district of the island, where he has large possessions. The observatory has been fixed at Belmont, a property belonging to this gentleman, on a site presenting very favourable conditions. M. de Chasales offered in the first instance the Isle d'Ambre, the scene of the well-known romance of *Paul and Virginia*, as the site; but various considerations, including the difficulty of access for landing the instruments, rendered that at Belmont more advantageous."

**PHOTOGRAPHIC IRRADIATION.**—Mr. Stillman, writing to *Nature* from New York, referring to the discussion on blurring or irradiation, says:—"In *Nature* vol. x. p. 245, Mr. W. C. Crofts adds his experience to those previously given in your journal, and gives his conclusion as opposed to that of Mr. Aitken. Like most conclusions based on incomplete evidence, it does not conclude anything. The fact is as I have stated it in my previous note on the subject, and when I return to England I will be most happy to demonstrate it to anyone who cares to examine the question thoroughly. Mr. Crofts' experience with the Liverpool dry plates agrees with my own, for these plates are prepared with a pyroxyline which gives a minimum of irradiation when backed, and give the best quality of image for scientific purposes attainable with a bromide film; but certain qualities of pyroxyline prepared in precisely the same way will show irradiation that nothing can cure, even when used for making transparencies by contact, where, of course, there can be no question of influence of any optical defects. The unquestionable fact that a collodio-albumen film acts in so totally different a manner from one of bromized collodion should prove that the lens has next to nothing to do with it. My conclusions may be very imperfect, but so far as they go they are definite, and are drawn, not from two or three, but from hundreds of experiments with all kinds of dry plates and many different samples of pyroxyline, and whatever they may be worth they fully support Mr. Aitken's views."

## To Correspondents.

**A LITTLE MAN.**—Add your permanganate very gradually, and in tiny drops, for there should be but the faintest tinge perceptible. Filter your bath afterwards, and test with litmus paper; if too acid, add a little fresh silver solution, but it will scarcely require more acid. We fear you have added too much permanganate.

**A YOUNG DISCIPLE.**—When you add the ether to the thick collodion, do you shake the mixture up well? If you do, and still the collodion sets too slowly, there is no help for you. Ether sometimes contains water, and if you have been adding two or three doses of ether, the water in these may still be in the collodion; in this case the latter would be slightly turbid.

**A. B.**—The defects may be due to methylated spirit, if the latter is rubbed over the photograph; but try a sensitizing bath rather stronger than usual, for the difficulty may proceed from the albumen becoming dissolved from the surface of the paper. It seems as if fibres on the surface of the paper, which were matted down in the first place, have shifted from their original position, owing to the surface being too severely handled. Hypo would scarcely produce the defects.

**F. J. DAUBAN.**—The Woodbury process is patented, and you must obtain permission to work from the Photo-Relief Company. When the intaglio has been secured on gelatine, this is hardened in alum, and an impress taken of it upon an antimonial lead plate, which then becomes the printing block. A little pool of transparent ink, made up of gelatine and Indian ink, is poured upon a sheet of very smooth paper, and the block is made to descend and press out all superfluous ink; after a few minutes the ink sets, and the block is again raised, and the impression dried, fixed in alum, and pressed.

**CURIOS.**—1. and 2. No restriction as to date is specified, but old or well-known pictures of past years would scarcely secure a prize in face of other productions. 3. For the prizes for series of three pictures, one series of each only should be sent; but for the prize for single pictures several might be forwarded. We fear your suggestion would avail little, for pictures by Robinson, Rejlander, Blanchard, Wortley, &c., would be distinguishable enough without any names being affixed.

**D. E. D.**—There is no doubt whatever that the stains are due to hyposulphite of soda. To make sure of the matter, we have tested with iodide of starch. You say the marks do not appear till after the prints are dry; this is very probable, especially as, in the photographs you forwarded, the stains are all in the same place, *viz.*, in the left hand top corner. The pictures have no doubt been faultlessly fixed and washed; but they must have become soiled with hypo as they laid in a heap one upon the other, and hence it is that the markings are in the same position in all of them. Perhaps the hypo is upon the presser with which you keep the pictures flat, or perhaps the hand of the mounter was soiled when he handled them. We carefully cut out the spotted portions and tested them, as you may easily do yourself. Make a little thin starch very carefully with distilled water; add to it a drop or two of a solution of iodine, which may be made by dissolving a tiny fragment of iodine in alcohol, or in an aqueous solution of iodide of potassium. Put a little of this blue iodide of starch into two test tubes (the blue colouring should be so faint as scarcely to be discernible unless a white paper is held behind), and into one of them put the fragments of paper that are stained; heat under a spirit lamp for a few minutes, agitating the while, and then pour the liquid into a third test tube of similar dimensions. Compare the liquid thus treated with that in the other test tube: if it has bleached at all, you may be sure hyposulphite of soda is present.

**TWIN.**—Enlargements on opal glass, produced as you mention, should be permanent enough if properly prepared. If the photograph is not, however, carefully fixed and washed, or if left unvarnished in a room lighted with gas, it will, of course, be liable to discolour. Collodion is more easily freed from hyposulphite than an albumenized surface.

**G.**—Several methods for photographing on wood have appeared in the *News*. Gravers will tell you that the main objection to photographic sketches on wood is the film upon which the image rests. This must be obviated, or reduced to a minimum, in order for the process to be successful. Whitening the wood block by rubbing on a little whitening is first of all necessary, and then a very dilute coating of salted albumen is applied, which is sensitized in the usual manner. The collodio-chloride process has also been used in America with some success, notwithstanding the film. The *Illustrated News* has made some slight use of photo-wood engraving, and there is no doubt it is employed by the *New York Daily Graphic*; but the methods are, we believe, secret ones. There is no difficulty, however, in producing impressions by using dilute albumen.

**G. F.**—The lighting is too uniform over the whole face; there should be more shadow on one side, to give relief and vigour.

**PRINTER.**—There is an article on "Vignetted Photographs," by Mr. Bovey, in the *Year-Book* for 1874, which will tell you something of the matter.

**AMATEUR.**—The photographic exhibition at Paris was to close, we think, on the 30th ult.; the time may have been prolonged, however. It is located in the *Palais de l'Industrie*, in the Champs Elysees, and therefore in a very convenient situation for visitors.

Several Articles in type are necessarily held over till our next. Several Correspondents in our next.

## The Photographic News, October 9, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### USEFUL APPLICATION OF PHOTOGRAPHY BY THE HOME OFFICE: GUNPOWDER *versus* PYROXILINE.—VISIBLE IMAGES UPON DRY PLATES.

*Useful Application of Photography by the Home Office: Gunpowder versus Pyroxiline.*—It is too much, perhaps, to expect perfect immunity from explosive substances so long as we manufacture and employ large quantities of gunpowder and other combustibles every day of our lives; but measures certainly ought to be taken to guard us as much as possible from mishaps resulting in the transport and storage of such materials. As long as we have heavy charges of explosives carried about in the neighbourhood of populous towns and cities, so long shall we be liable to such disastrous occurrences as that the other day at Regent's Park; for, exercise what care and precaution you like, human beings are not infallible, and one careless action suffices to bring about the most awful consequences. Our Home Office has, during the last half dozen years, sought to cope in some way with these disasters, and has appointed an inspector of explosive materials, whose duty it is to see that proper care is taken in the manufacture of gunpowder, &c., and due precautions observed in its transport and storage. More than this, he is instructed to inspect the site of any explosion that may occur, note the results carefully, and make an official report on the same. He is enjoined to make an especial examination of the damage done, and the particular injury inflicted upon the buildings, so that something may be learnt by experience as to the nature of factory, &c., best suited for the manufacture and storage of the material; and in the execution of this branch of his duty he has recourse to photography to aid him in depicting the scene as truthfully as possible. Every report the inspector makes is accompanied by photographic illustrations, which serve to corroborate the view he takes of the matter, and to show how far precautions which have been taken to prevent the effects of the explosion from spreading—such, for instance, as screens, mounds, ditches, intervals, &c.—have fulfilled their purpose. The camera rapidly sketches the whole scene immediately after the occurrence, showing, possibly, how and where the brickwork has given way; how the light roof above has been blown off with little injury; how strong bolts have resisted the force of explosion, and have been torn and twisted in consequence; how the hollow in which the magazine stood has served to arrest the course of the injury; how the water from the tank above has, in consequence of the explosion, flooded the building, and put out any remnants of fire. The Regent's Park calamity brings, however, other ideas to one's mind; and one point which strikes a photographer is, whether we are still employing the safest kind of explosive nowadays. Every photographer knows that pyroxiline or guncotton is a much more powerful compound than gunpowder, and now that our chemists have discovered that it may be detonated in a wet state just as well as in a dry condition if you only know how, it becomes a question whether our photographic material cannot be more widely employed than hitherto. Guncotton soaked with water is, as we know very well, not only incombustible, but positively unflammable under ordinary circumstances, and might even be used with advantage in extinguishing a fire, in the same way as a wet blanket. No danger could possibly arise from the transport or storage of large masses of such material as this, and it might safely be carried by rail or canal through our cities without the slightest prospect of its becoming inflamed. And yet, as we have just said, it is capable of being employed as a valuable explosive under special conditions. It can be thrust into a blast-hole in the rock sopping with water, or bundled into a cabbage net and thrown into the sea, and under

these circumstances can be made to explode with a terrific power, equal to that of five times its weight of gunpowder. The secret is simply this (a secret we owe, by the way, to one of our clever war chemists, Mr. E. O. Brown): although guncotton can only be exploded when dry by a fulminating powder, dry guncotton, on its side, can detonate other guncotton, whether dry or wet, and thus it is only necessary to initiate an explosion in a small dry charge in order to make a large quantity of wet pyroxiline take fire. Take a dry cake of guncotton, place it in the middle of a heap of wet, and then detonate it, and the whole at once blows up, the unflammable cotton being quite as destructive in its effects, under these circumstances, as the dry. "If so," the reader may exclaim, "a store or cargo of wet guncotton would be always dangerous so long as there was a small portion of dry material in the building also." This is not so, however. Dry guncotton can communicate *detonation* to wet, but not *inflammation*: in other words, if you set fire to a cake of dry guncotton with a red hot iron, any wet pyroxiline in the neighbourhood would refuse to ignite; but if you detonate the cake with fulminate powder—and then only with a fulminate of a special kind—the whole mass of wet and dry material will undergo combustion. So that it is only by means of a particular key that we can get to the exploding properties of wet guncotton, and, failing this, we can always rely upon its perfect safety. Under these circumstances, it seems to us matter for grave consideration whether pyroxiline should not be more universally adopted, both for military and for industrial purposes.

*Visible Images upon Dry Plates.*—Before developing some of Col. Stuart Wortley's dry uranium plates, the other day, we were surprised to find on several of the films a distinct outline of the image on viewing them by reflected light. Such an impression we never remarked before, and it is possible, therefore, that the action may have been rendered visible by the colour of the film, for this was the first time we had worked with bromide plates with stained collodion. The plates, too, strange to say, proved to be under-exposed, so that the action could not have been due to a prolonged exposure to light. By transmitted light nothing was visible, nor did the phenomenon occur on all plates that had received an equal amount of exposure. We propose coming back to the subject again shortly, confining ourselves on the present occasion to a bare mention of the fact.

### AMERICAN CORRESPONDENCE.

#### NEW METHOD FOR SILVERING PAPER—MAKING SOLAR NEGATIVES—COLLODION FORMULE—THE USE OF GRAPHITE IN THE NEGATIVE PROCESS.

Mr. M. M. Griswold, of Boston, gives the following new method for silvering paper:—

"The bath I use is from thirty to forty grains strong, containing a strong dose of nitrate of ammonia, and is alkaline from ammonia. The paper is immersed, face up, one at a time, until from ten to twenty sheets are covered by the solution. The dish being rocked back and forth to loosen bubbles and make sure that each sheet is thoroughly wet, I then turn the whole mass over, which brings the first ones immersed to the top face down. The next operation is as follows: have a sheet of double thick glass a little larger than the paper (I am speaking of whole sheets of paper), which place at a proper inclination to drain the surplus solution back into the bath. Float the paper to one side of the bath to get them even, then take them all out together, and lay them, face down, on the inclined sheet of glass, near enough to the top to be held with two wooden clips, one at each end: the drainage is now all back into the bath. To hasten this operation I use a squeezer—a strip of rubber set into a stick a foot or more long, which is applied lengthways at the top of the paper, and pressed forwards towards the bottom, forcing the solution out of the paper into the bath. If desired to secure the largest amount of silver absorbed by the paper, press the solution from the top sheet, then the next, and so on; or the whole can be

squeezed at once. What I claim for paper so prepared is, greater depth and transparency to the picture, and perfect uniformity in the paper, with facility, and equable toning. The paper prints clear through, giving great body to the darker parts. On the score of economy of silver, I think the loss less than when paper is hung up to drain (on the floor) in the usual way. The saving of time in silvering by this method would largely overbalance the waste of silver by extra absorption, if there be any.

"Here is another dodge I have lately suggested. You know that I have gone back to first principles, and use a flat dish for negatives. My dodge is a funnel for filtering into flat dishes. I call it the 'Hour-glass Funnel.' When the cotton or sponge gets dirty, turn it over, and run water through the other way: it saves bothering with bottles, &c.

Mr. J. W. Wykes touches a subject that has been much neglected—that of making solar negatives. His formulæ may help many others. He says:—

"I have tried every other method, and always go back to this with pleasure. If this will help some one that is making those hard negatives so annoying to solar printers to better results, I shall be repaid.

"*Bath*.—Forty grains of silver to one ounce of water; one-half drachm of nitric acid to sixteen ounces of solution. Use collodion of a deep colour, with about five grains of cotton to ounce.

*Developer*.—Water ... .. 20 ounces  
Iron ... .. 1 ounce  
Nitrate of potassium ... .. 120 grains

From Mr. C. A. Zimmerman, St. Paul, Minn., comes the following collodion formulæ:—

*Good Keeping Landscape Collodion for Cool Weather Use.*

Ether and alcohol ... .. equal parts  
Iodide of cadmium per ounce collodion ... 6 grains  
Bromide of cadmium per ounce collodion ... 3 "  
Cotton from 5 to 8 grains per ounce collodion.

"This will keep any length of time, and will, with proper handling, give fine, soft, and brilliant results. For this collodion double solution of iron developer is the best.

*Landscape Collodion for Ordinary Use.*

Ether and alcohol ... .. equal parts  
Iodide of ammonium per ounce collodion ... 2½ grains  
Iodide of cadmium per ounce collodion ... 2½ "  
Bromide of cadmium per ounce collodion ... 2½ "  
Cotton *ad libitum*

"Will keep moderately well, and give very brilliant results.

*Portrait or Landscape Collodion for Immediate Use.*

"Will not keep as long as above two formulæ.  
Ether and alcohol (equal parts) .. ... 1 ounce  
Iodide of ammonia ... .. 5 grains  
Bromide of ammonia or cadmium ... .. 2½ "  
Cotton as desired

From Mr. E. Bierstadt, of New York, I have the following interesting notes on the use of graphite in the negative process:—

"While the subject of 'graphite negatives' is yet fresh, it may be well to name a few other uses that are not generally known for graphite in photography. 1st. Ordinary negatives can be strengthened with it in this manner: after developing and fixing, wash well, and drain the plate, and pour on the dextrine solution at the upper corner, so that the water still on the plate may be driven off before the stream of dextrine; drain and pour over once more, and this time do not drain off too close, but as soon as the stream becomes broken into drops, bring the negative back to a horizontal position, and dry over a spirit lamp; then, with the negative laid face down on a dark cloth, expose the back side to strong light nearly one-half longer than would be required for making a negative; then the graphite must be applied as usual with a camel's-hair brush until the desired strength is attained. 2nd. A new negative can be made on the back of an old one. It will be remembered that a patent was granted some time ago for coating both sides of the glass plate with collodion, and developing both so as to make one diffused image on the back of the one in focus, so that prints might be made with all the soft effect of a retouched negative; with graphite this can be done after the sharp negative is made, or it can be made on the back of any old negative. Clean the back, and coat with the sensitive compound as for a negative; dry by heat, and expose the negative side to light, and apply graphite, as usual."

EDWARD L. WILSON.

## THE PRACTICAL PRINTER IN AMERICA

### XI.

#### MODIFYING AND RETOUCHING NEGATIVES.

THE improvement of negatives by retouching and other methods of modification is scarcely a duty which comes within the scope of the printer, but as none can know so well as the skilled printer the especial needs of each individual negative in order to secure good results, it is desirable that he should perfectly understand the various modes of improving the printing quality of the negative, and that he should be master of the various methods of modifying results. Masking with semi-transparent paper, roughly applying colour over some portions of the negative at the back of the glass, shading by exposure to light, and various other "dodges," become the legitimate work of the skilled printer. Mr. Hearn treats judiciously of retouching, and if the printer be able to effect those simpler operations in retouching which are confined to removal of defects, it will be well. Modifications of light and shade or expression should only be attempted by a skilled draftsman:—

"Before printing from the negatives they should be held up and studied by transmitted light, and if there is any way to improve them, then it should be done.

"The skill required in printing from the negatives does not consist in placing them in the printing-frame as received from the retoucher, and printing from them mechanically, by putting a piece of paper from the same sheet of sensitive paper on negatives differing greatly from each other, and then printing them all to about the same shade.

"The negatives, to warrant this treatment, should be very evenly made as regards lighting, exposure, &c., and this is not a very regular occurrence in the best of photographic studios. The negatives, as they are received from the retoucher, should, to be sure, in the majority of cases, be ready for printing without any further treatment of the printer; but I have, however, found this to be a very rare occurrence, very often, indeed, seeing negatives which are faulty in some particular place, and which can be vastly improved by a little doctoring before printing.

"This part of the printing is probably one of the most important, and the value of a printer is in a great degree determined by it. It may be well to state here, that in proving the negatives, we only take out the most objectionable imperfections in the face, and leave the final retouching to be done by the artists, when they have decided on the negatives they prefer.

"I will now take up separately the different parts of the negatives, and state the manner in which they can be improved.

"*The Background*.—Often there are streaks running through the background which should be filled up with lead to the opacity of the surrounding parts, when these streaks are not as dense as the rest of the background when viewed through transmitted light. Sometimes the background is very bad indeed, so much so that the pencil will not thoroughly remove the defects. In such cases the negative, besides being printed in a small vignette to get rid of a great proportion of it, may have upon the back of it, over those transparent parts which are likely to be visible in the print, some transparent colour. I always use for this purpose some Prussian blue. This colour should be laid over the necessary places in smooth and even strips; and then the background, according to how nicely this blue painting has been done, will print proportionately better.

"Often 'smoking the negative' is resorted to, which consists in moving constantly the back of the negative over a smoking lamp until the smoke has gathered on the negative to the right opacity. Then, after removing the smoke that may be on the face, hands, and other parts of the figure, you proceed to remove it from that part of the

background which prints the lightest on the print, leaving it on that part that prints the darkest, and then the smoke, if it is not too thick, will stop out about enough, so that the background may print pretty fairly in a vignette or illuminated print, as the case may be. Always print negatives with bad backgrounds in vignette style, if it is possible.

“For extreme faulty backgrounds it is best to make another negative of the sitter if it is possible, and not resort to the ‘smoking,’ &c., unless it is impossible to obtain another one.

“*The Shadows—The Face.*—The shadows of the face will now be taken into consideration.

“In life, all of the shadows of the face are transparent, *i. e.*, there is always plenty of detail in them.

“In a negative, however, this is often different, the shadows generally being quite black, more so by far in the majority of cases than they should be.

“Under the eye there is often a heavy line, and over it a very heavy shadow, which in life does not show so plainly as it does in the negative, partly because they are flesh colour, and because—unless the person is in direct sunshine—there are no marked contrasts between the light and shade; and even then, if we do not look for them, they are very seldom attracted by an eye unaccustomed to the studying of the different effects of light and shade throughout all nature.

“In a photograph, where everything is either black or white, with proper gradations, these shadows and lines are more observable than they are in life, on account of their printing black. These shadows, &c., to be *true* (at least, as far as possible) to nature should be removed more or less, according to circumstances. The lines under the eyes should then be removed in a great measure, in many cases (according to the age of the person, &c.) only leaving a *trace* of each line there, and they will then be as observable in the photograph as they are in life. The shadows under the eyebrows should then be very much removed, unless there has been considerable time given to the negative in exposing, and thus have obtained *soft shadows with plenty of detail*. As long as there are detail and softness to the shadows, there is never much need of having them lightened more than a mere trifle.

“In lighting the shadows in printing, young beginners often carry it too far—so far as to make the prints in the neighbourhood of the eye, or wherever the place may be, look very flat, and thus have an equally bad result, but in another way. About the eye there should always be a proper amount of shadow, so as not to make it look swollen.

“This lightening of the shadows can very nicely be done by stripping evenly or stippling some transparent colour on the back of the negative, exactly behind the place to be lightened. As has before been said, we generally use for this purpose Prussian blue, which comes in little cakes, costing about seventy-five cents per cake. It is applied with a suitable brush wet with a little water, and upon which a little of this blue is dissolved. The thickness of this colour can be determined only by a great deal of experience, and to blue-paint a negative nicely is accomplished only after considerable practice.

“The lines between the eyes can be touched out best by the use of a Siberian No. 2 lead-pencil. In touching them, do not take them thoroughly out, unless the scowl was occasioned by the strong light in which the sitter sat, and is not habitual.

“There are sometimes very heavy shadows occasioned in lighting—‘after the manner of Rembrandt’ (?)—and these shadows are sometimes so very heavy as to be displeasing; then it becomes necessary to soften them. This is done before printing by placing a proper coat of blue paint on the back of the negative and over the whole side of the face. Considerable skill is required in placing this on so large a place, because if it is not placed on even

it will print spotty. Sometimes there are heavy shadows under the nose, chin, and often in the ears. Treat as above.

“It is necessary sometimes to prepare the lights of the negatives for printing, although generally they are doctored during and after the time of printing. For instance: very often the lightest side of the face will be too light when the shaded side is fully printed, and to prevent this it is sometimes necessary to blue-paint (as we shall hereafter term it) the shaded side as described above, so as to permit the light side to print without overprinting the shadow one. Generally while printing, when the shaded side is done, and there is some detail on the light side, the print is taken off, and the blank, white side shaded or tinted a little in strong light, by permitting the light to pass through a suitable aperture, cut in a dark piece of paper, on that side to be tinted. More of this further on. Let this remark answer for the present:—Never do the shading as last described unless there is some detail on the light side, because if there is not, the discolouring of the light side will flatten it very much, and thus be the means of ruining the prints. Your object is to soften a little, and not flatten a great deal, and as before said, there should be some detail on that side to accomplish the desired result. In shading this side, a very few seconds’ exposure to the sunlight will suffice.

(To be continued.)

ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

b. Absorption by Transmission through Liquids.

16. In the experiments with liquids, the same plate glass trough with quartz sides was used as when solutions were employed, and the apparatus was arranged in exactly the same manner. Great care was taken in the purification of each specimen. The bisulphide of carbon, and indeed most of the other liquids, were rectified immediately before proceeding to experiment upon them.

The following table contains a list of the liquids operated

TABLE II.—*Diactinic Power of Liquids.*

Thickness of stratum 0.75 inch.

Name of substance.	Transmission of spectrum.	Relative lengths of spectra.	Remarks.
Water ... ..	170.5	74.0	
Wood spirit ... ..	116.5	20.0	With a faint impression of the rays about 156.
Alcohol ... ..	159.5	63.0	
Fousel oil ... ..	116.5	20.0	
Glycerol ... ..	107.5?	11.0?	Slight empyreumatic odour.
Glycerine ... ..	114.5	18.0	
Ether ... ..	112.5	16.0	
Chloroform ... ..	122.5	26.0	
Dutch liquid ... ..	132.5	36.0	
Oxalic ether ... ..	115.5	19.0	
Carbolic acid ... ..	104.5	8.0	
Benzol (C <sub>12</sub> H <sub>6</sub> ) ... ..	117.5	21.0	
Paraffine oil (C <sub>20</sub> H <sub>42</sub> +2)... ..	111.5	15.0	Specific gravity 0.831. Boiling point 360°.
Oil of turpentine ... ..	104.5	8.0	Slight yellowish tint.
Phosphorus (melted) ... ..	.....	0	
Bisulphide of carbon ... ..	102.5	6.0	
Oxychloride of phosphorus ... ..	.....	0	
Terechloride of phosphorus ... ..	.....	0	Retaining a little phosphorus in solution.
Terechloride of arsenic ... ..	101.5	5.0	Glacial.
Acetic acid ... ..	112.5	16.0	
Sulphuric acid ... ..	160.5	64.0	
Nitric acid ... ..	106.5	10.0	Specific gravity 1.3.
Hydrochloric acid... ..	152.5	56.0	Specific gravity 1.1.

on, and the lengths of the different spectra, in terms of the scale already explained (par. 7). The compounds included in the preceding table, with the exception of nitric and

\* Continued from page 472.

hydrochloric acids, are not simply solutions, but liquids to which a definite chemical formula may be assigned.

The starting-point for each spectrum was 96.5 upon the scale already adopted.

Of all these liquids, water and alcohol are the only two, except sulphuric and hydrochloric acids, which are strongly diactinic; water is eminently so, alcohol in a much less degree. No relation in this respect is traceable between common alcohol and the other alcohols examined, viz., wood-spirit, fousel oil, glycol, glycerin, and the phenic alcohol, carbolic acid. Bisulphide of carbon, the refractive medium employed in my earlier experiments, is singularly deficient in diactinic power, and is therefore eminently unfit for such researches.

*o. Absorption of Chemical Rays by Transmission through Gases and Vapours.*

17. In the experiments upon the absorbent action of aeriform media, the gas or vapour under trial was introduced into a brass tube two feet long, blackened on the inside, and closed at the end by plates of quartz, which were fitted on so as to form air-tight joints. The tube could be attached by a stopcock to the plate of the air-pump, and after exhausting the air, any gas could be easily introduced. In cases in which the gas was liable to act upon the metal a glass tube was substituted for the metallic one, and the gas was introduced by displacement. The tube when prepared was interposed at t, fig. 1 (par. 6), between the slits and the prism b, and the rays emanating from the electric spark were, after traversing the column of gas contained in the tube, received first upon the prism and lens, and then upon the excited collodion surface, in the usual manner.

When the vapour of a volatile liquid was to be examined, a few drops of it were generally allowed to fall into the tube filled with air, through which the vapour was allowed to diffuse itself at the ordinary temperature. The action of such vapours was therefore compared at a great disadvantage with that of the various gases, particularly where the volatility of the liquid was rather low. The results, however, even under these disadvantageous circumstances, were well marked, as may be seen by examining the subjoined table of gases and vapours submitted to experiment, in which the comparative lengths of the different spectra are shown in the second column of figures.

TABLE III.—*Absorbent Action of Gases and Vapours on the Chemical Rays.*

Length of column of gas 2 feet.

Name of Gas.	Termination of spectrum.	Relative lengths of spectra.	Remarks.
Atmospheric air ...	170.5	74.0	
Hydrogen ...	170.5	74.0	
Carbonic acid ...	170.5	74.0	
Carbonic oxide ...	170.5	74.0	
Olefiant gas ...	162.5	66.0	
Marsh gas ...	159.5	63.0	
Coal gas ...	133.5	37.0	Cut off abruptly.
Protoxide of nitrogen ...	159.5	63.0	
Cyanogen ...	159.5	63.0	
Ammonia ...	170.5	74.0	
Sulphurous acid ...	110.5	14.0	Cut off abruptly.
Sulphuretted hydrogen ...	110.5	14.0	Cut off abruptly.
Bisulphide of carbon ...	101.5	6.0	A few of the strongest lines
Dichloride of sulphur ...	108.0	10.0	between 140 and 152 are seen
Benzol ...	131.5	35.0	Faint beyond 111.5.
Oil of turpentine ...	152.0	55.5	
Chloroform ...	152.0	55.5	
Ether ...	163.5	67.0	
Terchloride of phosphorus ...	131.5	35.0	Very feeble spectrum.
Oxychloride of phosphorus ...	141.5	45.0	Fades out very gradually
Hydrochloric acid ...	151.5	55.0	
Hydrobromic acid ...	119.5	23.0	Cut off abruptly.
Hydriodic acid ...	111.5	15.0	Cut off abruptly.
Peroxide of nitrogen ...	0	0	
Peroxide of chlorine ...	0	0	

18. The absorbent action disclosed by the foregoing experiments on the colourless gases and vapours is very

interesting, as it proves that differences exist in the diactinic power of these substances quite as marked as in the ease of liquids and solids. Some of the elementary gases—oxygen, hydrogen, and nitrogen—appear to possess a diactinic capacity greater than any solid or liquid body. Many compound gases, such as ammonia, carbonic acid, and carbonic oxide, appear to rival them. Olefiant gas, cyanogen, and hydrochloric acid exhibit a decided but not great absorptive power, with which that of the vapours of ether, chloroform, and oil of turpentine at the atmospheric tension, and when diffused through air, may be compared. Doubtless if these vapours were tried at a tension of thirty inches, they would exhibit greater absorptive power. The absorptive action of hydrobromic acid much exceeds that of the hydrochloric, and that of hydriodic acid is greater than of either.

The abrupt termination of the spectrum in coal-gas is remarkable. The absorption appears to be due, not to the permanent gases, but to the vapours of benzol and other heavy hydrocarbons which it contains. The four compounds of sulphur—viz., sulphurous acid,\* sulphuretted hydrogen, bisulphide of carbon, and dichloride of sulphur—are especially active in absorbing the chemical rays; and the vapours of the tetrachloride and oxychloride of phosphorus exhibit a similar though less intense absorptive power.

(To be continued.)

A FEW WORDS ABOUT PRINTING.†

The matter of printing has already been the subject of many an article and discussion, and yet there are some branches of the subject in which we make no progress. Complains about albumenized paper have not yet ceased. Perhaps the albumenized paper makers themselves will aid us, now that they have given notice of an advance of twenty-five per cent in their prices, and they will supply us in future with a material which is twenty-five per cent better. Time will show.

Many a time the question has been asked: is there no better material than albumen from which a photographic material can be prepared? The number of experiments that have been made to this end are incalculable, and thus we have gelatine paper, amorph-paper, caseine paper, gluten-paper, collodio-chloride paper à la Ost, and collodion paper à la Obernetter, enamel paper, and heaven knows what besides, for in France there are still other sorts manufactured. Some very beautiful specimens have been secured on these materials, so that it is matter for regret that the experiments have again sunk into oblivion. Some of the papers have peculiar advantages. Such sharply printed pictures as those upon Obernetter's collodio-chloride paper I have never obtained on any other material, and the paper has besides a vigour and depth not possessed by an albumenized surface. It is always a difficulty to obtain a sharp and brilliant picture from a thin negative; but with Obernetter's paper the problem is easily solved.

The doubly coated albumenized paper is now-a-days recommended, the high gloss the paper possesses being due, probably, to the additional coating. This gives brilliant pictures, but not so vigorous as collodion-paper. One of the drawbacks of the latter is, of course, its tendency to break. Ost, however, says that this defect is easily avoided. Certainly the matter deserves a little more trial, for we shall otherwise remain sitting at the silver process for some time to come. Endeavours to bring forward the carbon process have proved unavailing. The latter was too uncertain, and only answered in the hands of those who were well skilled in its employment. Every photographer is aware of this. Just now the carbon process has been much simplified in England, and it is

\* An aqueous solution of sulphurous acid cuts off the spectrum at the same point as the gas itself does.

† Photographische Notizen.

said to be no more difficult to work than the silver method. Why, then, is it not adopted? On the one hand, probably, there is a lack of operators who understand the process, for the principal himself cannot give up his time to the matter; and on the other, the materials are doubtless too expensive. A sheet of pigmented tissue is said to cost about sixpence. For this money a sensitized sheet of albumenized paper may also be prepared. It is the same with *Lichtdruck*. Printing in pigments, and with greasy ink, are both very good things, but they do not appear adapted to all of us. Some very nice *Lichtdruck* prints are produced now-a-days, but everybody cannot produce them, and certainly not every printer. I have followed the subject with much interest for some time, but never had time to take the matter in hand myself, for to prepare a *Lichtdruck* block in order to print off a dozen portraits is scarcely profitable work. The silver process is less troublesome, and gives prints of a finer character.

Despite many efforts on our part, it must be admitted that we have as yet got no farther than the silver printing process. The operations of printing, toning, and fixing are the same to-day as they were sixteen years ago. It may be that we are in a position now to save our silver, for there is now paper already sensitized to be purchased in commerce. I saw some recently made by Talbot, of Berlin. This material is, however, not for the ordinary photographer, but for engineers and builders, for copying their sketches and drawings. The duplicates are printed without lens or negative. The drawing is placed in the printing-frame, then a sheet of the Talbot paper is put upon it, and the frame closed. On exposure to light, the black lines of the drawing keep back the rays, while the white portions allow them to pass, so that a negative on paper is the result. The process gives quite startling results, and those who doubt it should make the experiment. The paper negative is not toned, but only fixed, and then a positive may be produced from it in the same way. Why do not photographers employ this kind of paper? It is very good, for I have kept a piece of it for six months, and it is still perfectly white. It seems to me, however, that the pictures tone with difficulty; at any rate, my chloride of lime toning bath gives no agreeable results. M. Talbot himself has given no formula for a toning bath, and it would be well for him to do so. To many modest photographers the process would be welcome in case they did not wish to have resort to silver printing; for the employment of albumenized paper brings with it many defects, such as the discolouring of the bath, the dissolving of the albumen, the tinting of the surface on keeping, &c. All these would be overcome by having resort to a paper ready sensitized that would keep well.

I will admit that most of the defects to which I have alluded are easily removed, if one only knows how to go to work. There are, however, many who do not. I am acquainted with printers who put brown baths in the sunshine, or add kaolin to them. Such remedies were good enough when we knew no better, but now they are quite superfluous, since permanganate of potash is used in the studio. Two or three drops of a solution of this useful compound will render a brown bath again clear in an instant. More of the solution must not be added than is necessary; too much is injurious. Another point about which we often hear complaints is the production of weak prints by reason of poverty of the bath. One would think that the argentometer would indicate when there is too little silver; but, unfortunately, the instrument gives false results by reason of the bath containing other salts than those of silver. The only way of properly controlling is to employ the Vogel silver test. It is, however, seldom used, because many find it too troublesome, and with some people to take things easily is everything.

Acid in the bath is also readily removed. A few drops of carbonate of soda solution is sufficient for the purpose; but how seldom is this simple recipe adopted!

## Recent Patents.

### ORNAMENTING MIRRORS WITH PHOTOGRAPHS.

BY CHARLES SMITH.

THE following specification describes a mode of ornamenting mirrors with photographs and other designs:—

"The object of this invention is the use or application of mirrors and other plates of silvered glass for advertising, decorative, and art purposes generally. When desired, the lines, letters, figures, and ornamentation used therein can be so arranged that the silvered glass which has not been disturbed or affected by the process may retain its usefulness as an ordinary mirror. The glass may be cut or cast in any required or desired form or shape, and be used for ornamental panelling in furniture, on the walls and ceilings of rooms and buildings, and for various other decorative purposes; also for plain or ornamental notice or show-boards for advertisements and other similar purposes.

"The method of carrying the above object into effect in practice is as follows:—I take properly silvered plates of glass of the requisite size and shape, and remove therefrom that portion of the said silver or silvering which it is proposed to occupy or cover by the lines, letters, figures, or other devices or objects intended to be represented or exhibited. For lines, letters, and small devices I remove the silvering with a style, graver, or other finely pointed or sharp-edged tool or implement, either with or without the aid of a stencil plate cut to the required device, or by a brush or other instrument and stencil plate only. In the case of larger pictures, photographs, works of art, and other devices, I trace the outlines, shapes, or forms thereof on the silvering, and remove a portion of the same in the manner previously described, or by means of a brush or other instrument with a stencil plate of the required form; or the said silvering may be removed from the glass by any of the usual chemical agents capable of decomposing it or detaching it therefrom, care being taken in all cases to leave the edges of the silvering which is left on the glass as 'clean' or even as practicable. The lines, letters, and other such portions of the cleared glass are then covered with pigment, coloured paper, or other suitable material or materials, or frosted, or otherwise treated to render them visible, or to produce the desired effect. The larger pictures and other devices are placed in the spaces cleared to their respective shapes, and are secured therein by strong paper, cloth, or other backing on the whole or a portion of the silvered glass. The latter may be previously covered with paint or other suitable material, to form a ground or protection. Photographs and other objects thus presented to the eye will appear in high relief, and their general beauty and effect be greatly enhanced.

"Having thus fully described and ascertained the nature of the said invention, and the method of performing the same, I claim as new, and desire to secure by the before mentioned in part recited letters patent, the method of ornamenting mirrors, and displaying lines, letters, figures, pictures, works of art, and other devices thereon, substantially as and for the purposes herein described."

### ALBUMENIZED PAPER ON BOTH SIDES.

BY JAMES BECKETT.

THE method of albumenizing paper on both sides here proposed received provisional protection only:—

"This invention has for its object an improved system of treating paper by albumenizing instead of coating one side only. I immerse the paper in the albumen solution, thereby coating the paper on both sides at once. The paper may be coated on both sides by floating, but I prefer immersing as a quicker system.

"The object of this invention is to give greater stability to the paper, and thereby rendering it more impregnable to the various chemicals that it is subjected to in washing, toning, and fixing. By coating both sides of the paper with albumen the saving of chloride of gold is immense, and the hyposulphite of soda is prevented from entering into the porous or fibrous side of the paper, thereby rendering the prints more durable. With this paper five minutes' washing is sufficient, and blistering of the paper is prevented. Paper prepared by this system works well with my patent washing, toning, washing-fixing, and washing-machine."

## THE PHOTOGRAPHIC EXHIBITION.

It is scarcely necessary to remind our readers that the Annual Exhibition of the Photographic Society will open with the usual conversazione on Tuesday evening next, and that the display of the pictures competing for the prizes munificently offered by Mr. Crawshay will be held in the same room, and so form, in fact, part of the general exhibition. The exhibition will remain open for a little more than three weeks, closing on the fifth of November. On the Monday and Saturday of each week, and on the closing day, the exhibition will be open in the evenings from seven till ten o'clock, and so afford opportunity for operators and others engaged during the hours of daylight to visit the exhibition.

We hope and believe that the exhibition will be a good one, and that it will prove creditable and satisfactory to all concerned. As, however, in exhibitions planned and carried out under the most favourable circumstances, it always happens that some hitch, *contretemps*, or trivial blunder arises to cause disappointment to some one, it may not be out of place to bespeak patience and consideration in such cases, especially on the present occasion. The arrangements have been, from a variety of causes, inevitably somewhat hurried; the most desirable gallery for an exhibition could not be obtained; and the executive of the society and of the exhibition is, to some extent, new; and all these circumstances increase difficulties. We make these remarks, not in anticipation of troubles, but because, from two or three letters we have received, we find that a tendency to sensitiveness and irritability exists. Some correspondents write to complain of error and confusion in the repetition of the terms of the Crawshay competition. If such error had occurred earlier in the season, when it might have influenced the operations of photographers preparing specimens, it might have legitimately become ground of serious grievance; but, although error is always undesirable, this one could scarcely cause inconvenience to anyone now; for it is inconceivable that any of the negatives for competing pictures were still to be produced. Another correspondent points out that through the absence of a distinctive heading in the circular sent out, Mr. Crawshay's noble series of prizes may easily be read as a list of prizes offered by the society. Technically, a specific heading to the list of Mr. Crawshay's prizes would probably have been better; but no error can reasonably arise out of the matter as it stands. The whole matter is in truth too trifling for discussion, and we refer to it to deprecate the spirit out of which, we fear, such complaints occur, and to

urge upon all concerned a frank, manly spirit of good faith. The beginnings of strife are very dangerous, as all interested in the welfare of the society have reason to know. Petty disappointments, petty jealousies, petty ambitions, were the initial factors in the mischief which commenced twelve months ago. Let us hope that any repetition may be avoided on the present occasion.

## LAMBERT-TYPE.

We have recently had the opportunity, during two pleasant visits to the studio of Mons. Lambert in Paris, of witnessing the various operations which are included in the general term Lambert-type. Primarily, Mons. Lambert's process consists of a system of enlargement; but it is more essentially a simple mode of finishing negatives, whether enlarged or otherwise, by which the effect of much artistic labour is secured by the expenditure of a very slight amount of time and labour. Whilst not strictly new in some of its parts, it is certainly new in its systematic combination of the parts, and decidedly new in its results. In our next we hope to enter into details, but we briefly refer to the matter now in order to intimate that we hope to place a couple of specimens in the forthcoming exhibition, by the examination of which our readers will appreciate for themselves the character of the results more satisfactorily than they could after reading the most elaborate description. The examples are a couple we selected from the commercial work in hand at the time we were present, and to which we can testify as the result of extremely little labour. One of these—a group—we saw produced. The original negative had a plain background, which, being spotty and imperfect, was changed, in the manipulation, to the dim woodland background which it now presents, without, as may be seen, any trace of masking or outline. We shall have more details to give in our next.

## THE VARIED FORMULÆ OF DIFFERENT PHOTOGRAPHERS.

SOME years ago we published in the PHOTOGRAPHIC NEWS some account of the formulæ and manipulations of a number of distinguished photographers who had taken high rank in different phases of the art. The details were found to be varied enough to furnish matter for interesting comparison, and were at the same time sufficiently alike to warrant an apothegm we have often repeated, to the effect that success rests with the man, not with the method. Nevertheless, the method is not without importance, and most photographers read with eager interest information bearing on the precise mode of working of their successful fellows. Bearing this in mind, the editor of *Anthony's Bulletin* has conceived the happy idea of obtaining from a considerable number of his readers in America similar details to those to which we have referred, some extracts from which will doubtless interest English readers. We should premise that the photographers selected as able to give useful information are those whose pictures exhibited at the late Chicago Exhibition have possessed distinguished excellence. In many cases the responses to the editor's request for details of the mode of working are amusingly brief. One gentleman (Mr. Barhydt, of Rochester), whose portraiture is singularly fine, states that he uses "no unusual method, save care and skill." Another gentleman writes in very similar terms: he uses the "oft-published and well-known formula;" but if his work possesses any merit, "care, cleanliness, and practical judgment are the factors which have entered into the production of it." There are many letters (all published in full) to the same end. Here is a model example of epistolary brevity:—

"Mt. Vernon, O., July 31, 1874.

"DEAR SIRS,—We use Suttiff's amber collodion; bath, thirty grains; iron developer; fix with cyanide; T. and M. paper, silvered one minute on fifty grain solution. Dallmeyer lenses.  
Yours,  
F. S. CROWELL."

Mr. J. W. Black, of Boston, still adheres to his nitric acid bath practice. He says:—

"In reply to your question, I can only say that the process by which the best pictures I had at Chicago were made is the most simple and least troublesome one I have ever used, a weak bath from ten to twenty-five grains of silver, very acid; good, strong (or collodion with good body) collodion, sensitized with iodides and chlorides only; no bromides. It only wants a little skill and judgment to work in this way, and when once a person has become accustomed to it he would never go back to the old way of using bromides and strong and neutral baths."

Mr. E. R. Weston, the inventor of the burnisher bearing his name, an amateur whose portraiture is of the highest excellence, excelling much of the professional work we have seen, uses a silver bath unusually weak, and developer unusually strong, the former being a sixteen-grain solution, and the developer containing nearly a hundred grains of the iron salt to an ounce of water. Here is his formula:—

"I made those pictures at Chicago as follows:—Negative bath—fifteen grains; collodion—iodide of ammonium three grains, bromide of potassium half a grain; developer—iron eight ounces, water forty ounces, acetic acid sixteen ounces; paper bath—water sixteen ounces, alcohol four ounces, silver one ounce; lens—2A Dallmeyer; ridge-roof light, ground glass."

Mr. C. Gentile, of Chicago, sends some interesting details as to his lighting. He says:—

"My operating room is, perhaps, different to any other in the United States. The skylight had to be made to suit the building (or, I should rather say, the proprietors), as they would not allow the walls to be altered in any way. I have a northern light; the skylight is thirty-seven feet from the floor at the highest point. I also have a side light consisting of four large plate glass windows about three feet apart. With a little skill in working it I can say that I consider I have a pretty good light. As regards formula, I make my chemicals according to my light. I use my collodion more strongly iodized than I would under a different light. I also use a strong iron developer. Children's portraits I take in a few seconds; adults I generally sit from twenty to thirty seconds. I generally use a Voightlander lens, as I have a very excellent one."

Mr. C. H. Lanphear gives details of a curious experiment with collodion. Having had some trouble with spotty negatives, he says:—

"Having on hand a quantity of old red collodion, that was compounded before I used Mr. Anderson's formula, and composed of two or three different lots differently compounded, that had been poured together from time to time to get rid of—the remains of a lot that had ceased to work satisfactorily—I took this old collodion and poured into it a saturated solution of cyanide of potassium, a little at a time, till the colour was changed to a light straw, and an oily-looking substance was formed at the bottom of the mixture. After standing a short time, I decanted into a gallon bottle, and added that of Anderson's, which was working so spotty; and as the resulting compound was rather thin to suit me, I added a little more cotton, and the next day tried a negative with the best of results. It has continued to work good, either out doors or in."

Mr. J. Battersby, having no novelty in formula to communicate, describes his mode of producing a sheet of reproduced portraits which he exhibited. He says:—

"Tack a sheet of silvered paper by the four corners on a board, and expose to light for whatever shade your background is to be; tone and fix, of course, in the usual way, and mount upon cardboard. Cut out your figures with clean edges, and group and mount them upon the aforesaid with what taste and neatness you may possess. This picture can be copied to any size that may be desired for commercial purposes—carte-de-visite, cabinet, 4-4, or solar if it is desired in colours or India ink."

Mr. Daniel Bendann, whose portraiture we remember as of very high quality, says:—

"I place more stress upon cleanliness and proper arrangement of light than upon chemical excellence. I believe in simplicity; try to avoid humbug and sensationalism in pictures; endeavour to reproduce nature at its best, or, to use a homely phrase, 'with its best foot foremost.' I retouch but little; do not depend upon it at all. Five minutes is the average time required for retouching an imperial carte—oftener less than more. I do not permit my negatives to be touched by any substance whatever to give them a 'tooth' for retouching, not finding it necessary."

"My light is a due north skylight, the glass commencing seven feet from floor; pitch, fifty degrees precisely; glass part, fifteen feet wide and fourteen feet high. I use six opaque curtains on spring

rollers; in winter I scarcely ever make use of them. The above style of light I have always found the best; having thoroughly tried and built every other kind, I hold to that opinion. I can make every style and effect under it, inclusive of groups of ten to twelve persons: time of sitting, from ten to thirty seconds; children, two to five seconds. I do not believe in using reflectors, excepting in Rembrandts or isolated cases. They are false, and distort."

The last quoted sentence is somewhat puzzling. That by misuse of reflectors false and unnatural lights, destructive of true likeness, may be produced, is, of course, true; but reflecting screens can scarcely be said to distort. We next have from Mr. H. C. Wilt a printing and toning formula, by which, he states, he can treat a thousand card pictures with one grain of chloride of gold. Here is the formula:—

"Sensitizing Bath—forty grains; about one drop of conc. liquid ammonia to five ounces of solution; one ounce pure glycerine to a quart of solution; half an ounce nitrate of ammonia to a quart of solution; pulverised alum to a quart, about  $\text{O}$ . Shake well and leave to stand over night; filter, when it is ready for use. We use mostly brilliant paper, floating when warm about one and a-half minutes; cold weather, two minutes. After printing, soak the prints in a weak solution of chloride of sodium or common rock salt, a lump about so  $\text{O}$  to half a gallon of soft filtered water; when fully dissolved, soak the prints in this solution for a quarter of a minute; they are three-quarters toned then. Wash them in clean, soft water once or twice, then tone at once quickly. (Have ready), take fifteen grains chloride of gold, adding one tablespoonful of whiteing; then pour thereon boiling water until it changes from yellow to white, which will take from a pint and a half to a quart of boiling water. Do this in a bowl or dish; let cool, filter, and this is your stock toning. It will keep for years. To four ounces of this toning stock add one quart of blood-warm water. You are ready to tone 500 to 1,000 card photos. Keep up the temperature to about blood heat, and they will tone quickly, when wash and fix in hypo. soda, one ounce soda to twelve of water; fix ten to twelve minutes. (Caution.—You can easily over-salt and over-tone.) By this means you can tone on an average 1,000 card pictures with one grain chloride of gold, the most economical plan I know of. Having experimented for years, we now work thus. If the prints are over-salted or over-toned, they will look hard, grey, spotted, and coarse."

"After retouching a varnished negative, I lay the negative flat, face up, and warm, when the varnish melts, and the pencilling sinks or penetrates, and the varnish, being soft, covers over, and when dry prints much softer. You can also take a negative and set the intense side angling towards the light or sunny side; and, setting still or moving, you will find it to print softer than setting straight toward the sun; setting the thin side towards the sun, it will print much quicker and coarser. By thus angling a much softer and finer print can be obtained. Try it."

Mr. R. Benecke, of St. Louis, gives details of a negative bath with a large proportion of glycerine, which effectually checks any tendency to drying of the film during long exposure. Here it is:—

"Silver Bath.—Mix one part of good glycerine and three parts of water; put a few grains of nitrate of silver into it, and expose it to sunlight for a week or two. Make your silver bath of this in the usual way, using about thirty grains of silver to the ounce of fluid. Acidify with nitric acid. I have been using this bath now for over two years, for in and out-door work. The advantage is, a plate sensitized in it will keep good for hours. In going great distances I use the precaution to carry my plateholder wrapped in a wet cloth, after wetting it in and outside—the plateholder, I mean."

A large number of the communications contain the ordinary formulæ in use almost universally: a silver bath of from thirty to forty grains; iron solution of from fifteen to twenty grains to the ounce of water; printing bath from forty to fifty grains, in many cases with the addition of alum, as suggested by Mr. Anthony; and in almost every instance the sensitive paper is fumed. Borax is a good deal used to neutralise the toning bath, rule of thumb being the chief guide as to proportion. One gentleman uses equal proportions (about eighteen grains of each) of Epsom salts (sulphate of magnesia) in his developer. Almost all seem alive to the necessity of care and skill as of more vital importance than special formulæ. One states that you cannot say *how* you take a good picture, but that you must "feel it in your bones." Another recalls the "old, old story—chemicals worked with brains." Another says: "The great secret is to take lots of pains;" and no one will doubt that he is right.

## ON DEVELOPED PRINTS.

BY DR. LIESEGANG.

It is sometimes useful in photography, as well as in other branches, to look over results obtained many years ago. Thus, I lately found a collection of old plain paper prints, some of them printed on plain salted paper till the lights became of a deep blue colour, and bleached in an acid gold solution, a process much *en vogue* twenty years since. Those kept unmounted in a portfolio were unaltered, very rich in tone, the lights being yet white and pure, and all the half-tones of the negatives were certainly preserved. All those prints mounted on cardboard are yellowish and faded in the half-tones.

There were a few dozen large developed prints in the collection, made, as far as I can remember, fourteen years back. All those were mounted, and not one has changed in appearance. They were prepared after Sellbach's process. I do not know whether the formula has ever been published in England, but believe it might do some good to draw the attention of photographers to it who find difficulties in getting brilliant prints of a good tone by developing. Last month I saw photographers from Siberia and from Brazil, who told me they always used this process with good results. Thus it seems to stand all climates. The process is well suited for solar printing. To prepare the paper make the following solution:—

Rain water	...	...	...	2 ounces
Tapioca	...	...	...	20 grains
Iodide potassium	...	...	...	10 "
Chloride potassium	...	...	...	40 "
Lemon juice	...	...	...	16 drops

Mix the tapioca with a little water, dissolve the salts in the two ounces of water, add the lemon juice, and boil. Add the tapioca to the hot solution, and stir well in order to obtain a clear solution with no lumps in it.

This mixture is applied to the plain paper with a sponge, and with a second clean sponge it is lightly rubbed in, without in any way impairing the surface of the paper. After drying, the paper keeps unaltered for a long time. If it show red spots or stripes, do not care for them—they will disappear in the nitrate bath.

For sensitizing the paper use a solution composed of—

Water	...	...	...	2 ounces
Nitrate of silver	...	...	...	60 to 100 grains
Citric acid	...	...	...	5 "

The more contrast a negative shows, the less silver should be in the nitrate bath. Let the paper dry in a dark room: it is exceedingly sensitive to light. Print till the outlines of the image are visible; then mix one part of a saturated solution of gallic acid with four parts of rain water, and float the print on it, of course the image in contact with the solution. It soon becomes vigorous. You lift it from time to time at one edge to watch the progress of development. The print will be of a deep brown colour. As soon as the print is sufficiently developed, float it, in the same way, upon water. After a few minutes, steep the print in another bath of pure water, wash it well in several changes of water, tone in an old, weak gold bath, and fix in hyposulphite of soda; wash as usual. I do not know of any better process for developed prints having been published.

## ON PRE-LIGHTING THE NEGATIVE.

BY SAMUEL PRY.

SINCE the time—early in the present year—when you were good enough to insert a communication from me on the above subject, it has attracted much public attention, and the value of the principle has been admitted. As usual, some, who try it improperly, fail, and denounce the thing; others condemn it without trying. As the time of year is approaching when, if there is anything in it, it would be

of value, I may perhaps ask you to give me a little space to refer to some practice with it; and, in the first place, to suggest a crucial experiment which, in my view, includes the whole question.

Take an ordinary carte camera, with a shifting back to take two pictures on one plate; focus a three-quarter inch heel and bust as usual for vignettes, having a very light vignette background behind. Give a suitable exposure (say fifteen seconds); now remove the light-coloured background, and place a dark one behind; give the second picture also exactly the same time; now develop both at once, and what is the result? We all know perfectly what it is: that if fifteen seconds is the right time with a light background, it is quite insufficient with a dark one. A very obvious difference is seen in the two pictures, that on the dark ground being quite under-exposed. In this case the light background plays the part of the opal glass.

It is in dark weather, and with large pictures, that the advantage of the opal pre-lighting is most obvious. In working with a lens to take twelve-inch portraits—which requires exactly three times the exposure necessary for a carte—I am able to shorten fully one-half. This is a most important matter.

I propose to exhibit at the South London Society's Technical Meeting on the 15th, a 17×14 negative taken of the president, to illustrate the principle. The day when he sat to me was an intensely hot afternoon in August, about half-past three, with a stifling, yellowish haze very bad for photography. The exposure was forty seconds; and nothing under two minutes would have sufficed without the pre-lighting.

Some who have given an inordinate length to the pre-lighting get only fog for their trouble; those who have given insufficient find no result. In taking groups it is most valuable.

## NEGLIGENCE IN WASHING NEGATIVES.

M. L. G. KLEFFEL calls attention to the serious consequences of varnishing negatives before they have been sufficiently washed, and complains that frequently the reason of a varnish not adhering to the glass is put down to the former not being of good quality, while in reality it is not the varnish, but the carelessness of the operator, that is at fault. If the defective film is not much handled, the fault may not be apparent for some time; but as soon as you begin to work upon the surface—retouching, perhaps, with a pointed pencil—the lac breaks away, and leaves the image bare and unprotected.

In a recent number of the *Notizen* M. Kleffel quotes an instance of a friend of his having forwarded him a negative, with the remark that the varnish he had used appeared quite unfit for the purpose, and requesting an examination of the film where it had left the glass on being touched by a soft lead pencil. As he was quite convinced the varnish was not at fault, he determined to examine the plate carefully, to ascertain the reason why it sprang so readily from the glass surface. A careful inspection under the microscope showed what he had before suspected, namely, the presence on the surface of tiny crystals on those portions of the negative where the varnish had sprung away. These crystals were of course nothing else but minute particles of hyposulphite of soda, which had crystallised out of the film as soon as the latter had become dry.

This proved very clearly that the plate had not been sufficiently washed, and that the fixing agent employed had not been entirely removed; hence it had been formed into crystals, which refused to combine with the varnish, and the latter, having no support, gave way as soon as it was touched by the pencil.

This fact, says M. Kleffel in conclusion, shows that if hyposulphite of soda is employed in fixing negatives, too much care cannot be taken afterwards in their subsequent washing.

### THE ACTION OF COLOURING MATTER UPON THE SENSITIVENESS OF SILVER SALTS.

THE *Photographische Mittheilungen*, speaking of Dr. Vogel's experiments with bromide of silver, states that recently M. Edmond Becquerel has communicated to the Paris Academy of Science the results of researches that have been undertaken on the subject, upon his invitation, by M. Deshaies, of the *Conservatoire des Arts et Metiers*. These experiments were undertaken with films stained with coralline and aniline green, and were crowned with perfect success. M. Deshaies did not, however, confine himself to the use of bromide of silver, but continued his experiments with iodide of silver also, and obtained similar results. Dr. Vogel confined himself to bromo-iodide of silver, and, as he found here a marked sensitiveness for the blue rays, he did not continue his experiments.

M. Becquerel, moreover, essayed a colouring matter which Dr. Vogel did not try, namely, the green chlorophyll. Although collodion tinted with this possessed but a very slight greenish tint, the spectrum image secured with it was far broader than that obtained with ordinary collodion. Uncoloured collodion gave a picture between the ultra-violet and the blue—that is, the lines G and F—with the well-known maximum of energy near G; while with chlorophyll the greatest action was from the ultra-violet to line E in the green, while at the same time a weaker, but more noticeable, impression from E to B in the red, with a vigorous mark between C and D, was to be seen. On closer examination of the spectrum image, a second mark, of less intensity, was visible near the principal ones towards the red between C and D, and other weaker marks appeared in the green.

The most important confirmation of Dr. Vogel's discovery is afforded by the circumstance that the marks between C and D correspond with the absorption lines of the chlorophyll contained in the collodion. This result Becquerel obtained with every plate, and with various samples of collodion containing different quantities of chlorophyll dissolved in it.

It is interesting to observe that M. Becquerel does not seek to explain the cause of Vogel's results by attributing them to the action of continuing rays in the same way as Dr. van Monckhoven.

### EXPERIENCE WITH DRY PLATES.

BY J. BRIER, JUN.

IN answer to your request, I send some of my experiences with dry plates during the present year. I commenced with Capt. Abney's albumen beer process, and found it very good at first, but I had a great failure with one lot, through getting some fresh beer, which contained a great amount of salt, and made the plates slower day by day, so that the plates exposed two and three weeks after preparation were utterly under-exposed compared with the trial plates exposed soon after preparation. I found that applying a wash of aceto-nitrate of silver, as in Mr. England's process, made the plates more sensitive, and that the same method of preparation applied to pure bromide films gave plates nearly as quick as the wet, and without blurring, though no backing was used. During the spring I made a thorough set of experiments on the best way of drying plates. I had previously dried my plates (gum-gallic and collodio-bromide) in a box with an iron bottom and Bunsen's burner underneath, and a lantern chimney at the top. The result was, that I found drying spontaneously in a well-ventilated painted wooden box to be the best method. The box holds about a cubic yard of air. Each plate rests with the long thick edge at the bottom on two glass supports laid on fourfold blotting-paper, and shaped like a double-headed mushroom, and the back of the plate rests against two mahogany pegs in the side of the drying box.

I leave the plates undisturbed for at least twenty-four

hours, for if the box is opened before they are dry, there is sure to be a mark across the plate. I found that inserting a leaden trough of sulphuric acid dried the plates in two hours, but it made them less sensitive, especially for about two inches at the thin end, which, of course, would not do at all. It is well to nail the box up against a wall, as the air is driest at the top of a room, especially if the workroom is a cellar, as mine is, I am sorry to say.

In June we had some very fine weather, which stopped my supply of tap water, so I had to take to a process which needed but little washing. I used Mr. Davies' albumen beer process very successfully, but found them quite as slow as the old Taupenot plates; and the uncertain quality of beer led me to seek a substitute, which I found in Cassava gum, which is a lightly calcined powder used in calico printing for thickening colour; it is soluble in cold water (or should be, if sufficiently calcined); it is not as fond of moisture as gum-arabic, and does not produce the faintest trace of blistering in a film on albumenized glass; it may be used with pyrogallic, gallic, or acetate of morphia, to apply to a thoroughly washed, highly bromo-iodized film, but a backing will be required. I use a mixture of lampblack ground with india-rubber solution, benzine, and Bates' black varnish; this is painted on the back of the plate, and dries immediately. It is easily removed by moistening with water, and rubbing off in lumps with a piece of ink-eraser or india-rubber; and as it is mixed with rubber solution, it never gives off any dust to spoil the films.

But my practice has satisfied me that the best results are to be obtained on plates which do not require staining or backing to prevent blurring on the back of the glass and irradiation in the film. Albuminate of silver seems to answer this purpose most effectually. I like Mr. England's method of applying it, but as I have to consider my water in washing, I have devised a simpler method, which is quite as effectual. Here is the process. I make the following solutions:—

No. 1.—Plain prepared albumen	...	2 drachms
Twenty-grain solution of bromide of potass	...	¼ drachm
Forty-grain solution of nitrate of silver	...	1 "
Strongest ammonia liquid	...	½ "
Water	...	4½ drachms

This solution is sufficient for six 8×5 plates, does not need filtering, and will keep a week or so in the dark in a stoppered bottle.

No. 2.—Light Cassava gum	...	20 grains
Acetate of morphia	...	10 "
Acetic acid	...	20 minims
Sugar-candy	...	5 grains
Distilled water	...	1 ounce
Saturated solution of carbolic acid	...	2 drops

This keeps well, and must be filtered through scoured flax after coating each plate; it can be used till it gets weak.

I use patent-plate glass albumenized with a solution of one to forty of distilled water. The plates are put in the drying-box to keep them free from dust. The collodion must be made with a powdery pyroxiline, with the addition of a grain each of bromide of cadmium and ammonium to each ounce, with the usual iodiser. When the plate is coated, it must be allowed to set well, and immersed at least ten minutes in a forty-five grain, half-iodised, and thoroughly filtered nitrate bath. I filter through explosive gun-cotton rammed into the neck of an inverted wine bottle with the bottom knocked out.

When the plate is removed from the bath it is immersed for about five minutes in each of two dipping baths of distilled water, then drained a little, and flowed with the alkaline albuminate of silver solution No. 1 for about a minute, then washed most thoroughly under a tap of filtered common water, which may (excepting the first

small portion) be run into a bucket and put back in the filter for next plate; the plate is now drained, coated well with solution No. 2, and put in the drying-box on the glass rods.

The exposure should be about four times as long as for wet plates for (say) the first week after preparation, after which it should be increased as the plates get older. I have found this rule to apply to all dry plates except the Taupenot, and they cannot afford to lose any sensitiveness. I like Colonel Wortley's developer best for these plates, as it brings out the most detail with least fog.

I have no remarks to make but that I have found it the best process that I have worked (except the wet): but there is room yet for great improvement in dry plates. I intend to endeavour to add the albumen to the nitrate bath, and so do away with one of those tedious washings, for the simpler the preparation the greater will be the freedom from spots.

### PREPARATION OF PORCELAIN, ALBUMENIZED PRINTS, ETC., FOR WATER COLOURING.

BY CHARLES KNIGHT.

MUCH difficulty is often experienced by miniature painters, and those who tint photographs in water colours, in obtaining a surface free from greasiness which shall take the colour kindly, so that ox-gall and many other unpleasant preparations have been used when the more frequent and ready means—licking the surface with the tongue—has failed. I think, too, that there are very few who colour a great number of photographs but will be very glad to leave off this old and unpleasant habit, if they can find an inexpensive, pleasant, and at the same time a more efficient preparation.

Let the reader take the white of one egg (a French one will do for the purpose) and beat it to a froth; when the greater part has settled again, and has, to all appearance, returned to its former state, throw away the froth remaining, and mix with the liquid portion about ten ounces of water; then filter, and add afterwards a small piece of alum (if required to keep long) and cork the bottle after using.

With this preparation you can, without difficulty, overcome all greasiness, and a quantity costing one penny will keep at least a month.

### COMBINATION PRINTING.

BY F. M. BELL SMITH.\*

IN making composition pictures my plan and means are very simple. Having ascertained the number of figures to be introduced, their ages, sex, &c., I proceed with pencil or crayon to make a rough design. I then have a negative made of each, separately or in a number of small groups—say two or three in each—taking care to have the light coming in all the pictures from the same direction (unless the picture should be one where false lights are introduced, such as an interior with light from lamp on table, or in chandelier), and taking, also, particular care to have the relative sizes of the figures in proper proportion, not merely in perspective, but in relation one to another. Having now got a good negative of each of the parties, I get a print from each, and, roughly cutting them out, I arrange them on a sheet of cardboard covered with brown paper (a good quality of wrapping paper will do), pasting them on in the places I intend them to occupy in the finished picture. Now I see at once if I have got any in wrong proportion; if so, I get another negative taken at once, before proceeding further. When I have at last got all as I want them, I have the negatives retouched, and make my prints. Now, in making the prints for these composition pictures a great deal of care and judgment are required. We will say all the negatives are of

equal strength: well, if the picture is well arranged and in good perspective, there must be aerial perspective as well, and, therefore, the figures in the distance must be a great deal fainter and flatter than those in the foreground.

To produce this effect, care must be taken to print the prominent figures as strong as possible, and, in proportion to their size in perspective relation, make the others fainter. The plan I adopt is to print the distant figures very light, allowing the face to print more than the rest of the figure, and then sun them a little more in proportion as they are distant.

As most of these pictures are made for the purpose of copying, it becomes necessary to avoid showing the lines round the edges of the pictures which are cut out and pasted on the surface of the large picture. This I do by laying the print, after it is cut out and perfectly dry, face down on a piece of glass, and, with a sharp knife, paring the edges, so as to make the edge of figure, when pasted on, as thin as possible. With regard to the background, &c., I can only say that it requires an artist to paint one: but a very nice effect may be produced by selecting a nice view—say a grove of trees, or shore of a lake, river-bank, or some other pretty place—and enlarge it to the required size: print it on plain paper, and introduce your group in the way above described. A family might be taken in the grounds surrounding its house, with the residence in the background. The chief difficulty in the way of making family groups in interiors is, that the room and furniture would have to be carefully drawn by an artist.

In conclusion, I would say that my experience is, that there is no money in this kind of picture unless done with great dispatch, and a number of copies guaranteed at good prices. One hundred dollars is the lowest that any artist can afford to make one of these groups for.

### Correspondence.

#### TECHNICAL EXHIBITION MEETING OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR.—I shall feel obliged if you will kindly permit me to call attention to the forthcoming Technical Exhibition Meeting of the South London Photographic Society, and to explain its nature.

It will consist, not of an exhibition of pictures, but of various appliances of an improved kind that are employed in producing pictures. We invite the exhibition of all kinds of apparatus that have any novelty or improvement beyond those in general use. We also invite short, pithy papers of a strictly technical character. Any one who has something fresh that he has worked out is invited to contribute, whether it is derived from the glass room, the dark room, or the field, especially if illustrated by a specimen. Patented articles, and the results of secret processes (if they be distinctly so stated) will be eligible.

Opportunity will be afforded, as far as possible, for working a process or making an experiment in the presence of the meeting. Questions may be asked in relation to the articles exhibited, and information may be given; but the time will not permit of discussion.

Full particulars of the time and place of meeting will be published next week; any further information I shall be happy to supply.—Yours faithfully,

EDWIN COCKING, Hon. Sec.

57, Queen's Road, Peckham, S.E.

### Proceedings of Societies.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held on Tuesday, the 29th ult., at the Free Public Library, William Brown Street, the Rev. J. D. RILEY, vice-president, in the chair.

The minutes of the previous meeting were read and passed.

\* *Anthony's Bulletin*.

Mr. J. A. FORREST exhibited several 16 by 12 negatives of the lake district, and two were chosen from which the presentation plate should be taken.

Mr. A. TYRER exhibited several fine prints taken at Miller's Dale, which were much admired, and a wish was expressed that, if the other negatives selected were not suitable, the presentation prints should be taken from Mr. Tyrer's.

The Chairman showed a number of prints of Pantasaph Church and Monastery, taken by the wet collodion process.

A portfolio of views taken at the Africau diamond diggings, called "Gems from the Diamond Land," by Messrs. Gray Brothers, were examined with much interest. They were kindly lent for exhibition by Mr. G. F. Chantrell.

Negatives were handed round taken by the new emulsion prepared by the Liverpool Dry Plate Company, and exposed by Mr. Weber, the Secretary, and others, all of which show the excellence of the emulsion.

Mr. PHIPPS handed round some negatives taken at Dolgelly with the same emulsion, and some taken of his own preparing. They were all so good that Mr. Phipps was requested to state his method of preparing them. Mr. Phipps explained that his first experiments in the preparation of the emulsion were made with collodion bromised with cadmium only; and though he tried various organic additions to induce density, he was unable to obtain it. Subsequently he tried a collodion containing bromides of cadmium and ammonium, and there was a marked improvement in the result. Finally, he used a collodion bromised with ammonium only, and this gave a still better result. The image was capable of being brought out by plain pyrogallic acid, by which the exposure could be judged of with great accuracy: there was no difficulty about the intensity. After the formation of the collodio-bromide it was filtered into a dish and allowed to thoroughly set, then washed with distilled, and subsequently with ordinary, water. The thick film, being broken up into small pieces to facilitate the removal of the soluble salts, was, after a thorough washing, squeezed as dry as practicable, and treated with three or four doses of alcohol (filtered) for the purpose of absorbing the water contained in the broken film. Finally, sufficient of a mixture of ether and alcohol was added, and the operation was complete. No organic addition whatever was made to the collodion. He had kept emulsions prepared in this manner for about two months, and had no doubt it would be found to possess indefinite keeping qualities. The plates were prepared by flowing over the collodion in the usual way, and allowing it to dry. In developing he followed the printed instructions issued by the Liverpool Dry Plate Company. Great latitude was allowable in the exposure. If the preliminary treatment with plain pyro showed that the plate was over-exposed, it could be continued until all the detail was out, and intensified by the addition of acid silver. He exhibited a negative developed in this manner. If the light was bad, the strong alkaline developer was preferable. Mr. Phipps promised to experiment further, and give definite formulæ at the next meeting.

Mr. LEWIS HUGHES then described, by the aid of diagrams, several improvements he had been making in the working of the heliostat attached to his camera for enlarging microscopical objects. Some exceedingly fine microscopic enlargements were exhibited by Mr. Hughes.

The meeting was shortly afterwards adjourned.

#### PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.\*

A MEETING was held on June 2nd. President, H. J. NEWTON; Secretary, O. G. MASON.

Mr. CHISHOLM stated that he had been making experiments in the production of enamels on glass. He had used a blue glass, and also a red glass, on which he made silver transparencies, and baked them in a window glass stainer's oven, producing a brilliant yellow picture having all the beautiful gradation of tone without loss of detail.

Mr. CHISHOLM said that he had met a gentleman who was using chloride of palladium as a re-developer, and he considered the compound useless for such a purpose.

The PRESIDENT stated that he had used it for a year, and it had worked well. It was just as intense when varnished as when wet. His formula for an intensifier to strengthen negatives was as follows: water, one ounce; iodide of ammonium, three grains; nitrate of uranium, five grains; proto-sulphate of iron, ten grains, put together in the order given, not to be used until after two days old. At any time for two years after that it would be good, and the

older the better. He generally used it about half the strength given, by reducing with water.

Mr. BIERSTADT inquired if this re-developer would intensify strong enough for fine work.

The PRESIDENT.—You can obtain great intensity for that by using bichloride of mercury.

Mr. BIERSTADT.—I do not like the bichloride of mercury. The work of the Actinic Engraving Company is done in that way, but I do not like to use it.

After the appointment of an experimental committee, the meeting adjourned.

### Talk in the Studio.

THE MAYOR OF LIVERPOOL.—We have been favoured by Messrs. Vandyke and Brown with some admirable card portraits of Andrew Barclay Walker, Mayor of Liverpool, who has recently earned the lasting gratitude of that city by his magnificent gift of the new art gallery to the town. The photographs are unusually fine, and illustrate how skillful tonching may give finish without destroying texture, vigour, or likeness.

SCIENCE IN THE PHOTOGRAPHIC SOCIETY.—A correspondent sends us a cutting from *Nature*, and some angry comments thereon. The paragraph sent announces the forthcoming exhibition, and hopes that the present opportunity will not be allowed to pass without illustrations of what photography has done to advance pure science, concluding by remarking that "Mr. John Spiller, F.C.S., has been elected president, and Mr. R. J. Friswell, F.C.S., Hon. Sec. of the Society, so that the interest of science will have a good chance of being in future attended to." Our correspondent protests against the tone of patronage assumed by our contemporary, and adds that "photography and the Photographic Society have done quite as much for pure science as pure science has done for them." He further begs to remark that without questioning the scientific positions of the esteemed gentlemen named, it is an insult to assume that men like Mr. James Glaisher, F.R.S., and Mr. Baden Pritchard, F.C.S., were inferior in scientific position, "so that," under their presidency and secretaryship, the interests of science could not be looked after." We think our correspondent is unnecessarily sensitive. The paragraph was doubtless intended to be friendly, and if there is anything questionable in the wording, it probably arises from ignorance, our contemporary possibly not knowing who were the former officers of the society, as it would scarcely have implied that the director of the Meteorological Department at the Royal Observatory was not a fitting representative of science in the Photographic Society.

SEMI-OPAQUE GLASS.—The *English Mechanic* gives the following as a matt varnish:—"To half an ounce of white hard varnish add two ounces of methylated spirit; shake up well, and allow it to settle for an hour or two. Clean very carefully a plate of glass, and coat with the varnish. When dry, a semi-opaque film of exquisite fineness will be left on the glass, which answers well as a substitute for grinding the glass."

OBITUARY.—On the 30th ultimo, suddenly, after a long and severe illness, J. F. Trull, photographer, Falmouth, aged 45 years.

REPORT OF THE PATENT OFFICE.—The report of the Patent Office for 1873 just issued contains the usual details of the number of patents applied for, granted, &c., and accounts of income and out-going expenses. It appears that during 1873 there were in all 4,294 applications, of which 1,388 were only provisionally specified. Of these 68 applicants obtained grants of letters patent, but neglected to file final specifications, and 1,320 did not proceed after the six months' provisional protection had expired. 2,906 completed their specifications and obtained letters patent. In the preceding year, 1872, there were 3,970 applications, and 2,745 completed patents. Of the specifications sent in, 216 were filed complete at once without any prior provisional specification. During the year 737 patents paid the £50 stamp duty due at the end of three years (these were patents taken out during the year 1870, in which there were 3,405 applications, and 2,146 completed patents). There were also 232 patents on which the duty of £100, due at the end of the seventh year, was paid (these were patents taken out in 1866, in which year there were 3,453 applications, and 2,106 complete patents; the £50 duty on them was paid in 1869, when 578 paid that duty). There were 14 patentees who

\* Condensed from *Anthony's Photographic Bulletin*.

required duplicate copies of lost original patents. There were 3 new patents granted under the special provisions for extension made in the Act of 1852. The total revenue of the office during the year was £144,761, of which £2,290 was derived from the sale of specifications, &c., and the remainder from the fees on patents. Against this are to be set costs and charges to the amount of £49,477, leaving a surplus paid to the Treasury of £95,284. The corresponding amount last year was £85,611; and the total amount from 1852 is £1,108,204.

**WILSON'S PHOTOGRAPHY.**—Mr. Wilson has long enjoyed the practical monopoly of Scottish scenery, as a photographic artist. His work is generally good, and often merits higher commendation. His prints are always clear and uniformly sharp, if sometimes a little dark; and, in general, his selection of the point of view leaves little to be desired. For extent of view and management of distances he has never been surpassed, inferior workmen being generally contented if they can secure "bits" here and there, all foreground and middle distance. In several of his mountain views our artist is particularly happy in the way in which he manages to pick out on the plate the bright patches of white, which exactly imitate the latest vestiges of the winter's snow still lingering in shady hollows among the hills. The richly wooded scenery of the glens, the vast expanse of the mountain sides, the calm beauty of the lakes, are rendered with rare truth. The moonlight scene on the beach at Golspie will puzzle many a tyro in the art to know "how it's done." Perhaps the pure atmosphere of Aberdeen, in which city Mr. Wilson has taken up his residence, may have something to do with the printing. The specimens which he has sent us comprise views in all parts of the country, but they form portions of the various series which he has prepared for tourists who may wish to bring away with them some memento of their trip of a higher class than the common things usually sold as "Views."—*Bookseller.*

**FOR RETOUCHERS.**—Louis Burno says, in our "Western" namesake:—"Take the bath brick used for scouring purposes, shave it very fine with a knife, then rub thoroughly with the fingers, and sift through fine muslin into a bottle or box. Rub over negative in usual manner."

### To Correspondents.

**D. A.—1.** In preparing your collodion, something depends upon the nature of the pyroxaline you use. If you want to employ methylated alcohol and ether, take of each a pound or twenty fluid ounces, and dissolve in it about two drachms of pyroxaline. Try iodizing with ninety grains each of the iodides of ammonium and cadmium, and fifty of the bromide of ammonium. 2. What sort of an emulsion do you wish to prepare—bromide emulsion for dry plates, or collodio-chloride emulsion for positive printing? You will find ample directions for both in our YEAR-BOOK for 1874.

**CHARLES KNIGHT.**—We should advise your mounting first and glazing afterwards, the course most foreign photographers adopt; the moisture from the mounting material is otherwise apt to impair the glaze of the prints. You might, however, mount with india-rubber cement—india-rubber dissolved in benzole—without any fear, we should think, of injuring the glaze. A strong bath, newly made, is sometimes apt to bite into the collodion plate as you describe. You do not send any enclosure, as stated in your note. The carte of the Crown Princess of Prussia is a most successful example of out-door photography.

—To employ an old dipping bath for sensitizing paper it is necessary first to remove the iodide. Make a solution of citric acid, sixteen grains to the ounce of water, and add one drachm of this for every eight ounces of solution. Add some ammonia, drop by drop, until red litmus paper becomes blue. Filter, and then make up the silver solution to the strength you require for sensitizing paper.

**W. A. B.**—Marine glue may be used as a cement for glass vessels intended for holding solutions of nitrate of silver with perfect safety. It is made by incorporating india-rubber and resin; but it can be purchased more easily than made. It is generally kept at tool shops. 2. It is probable that a cork thoroughly saturated with paraffine might be used in contact with nitrate of silver solution without injury; but we cannot say with certainty whether it would be easy to sufficiently saturate the cork with the protecting substance. A glass stopper is safer.

**T. H.**—It is desirable to select a night when the moon is very bright to secure a good photographic image of its face, so as to secure, as nearly as possible, an instantaneous picture. If any sensibly prolonged exposure be given, the image will be blurred, from the motion of the moon and earth. 2. On a very bright night the brilliantly illuminated edges of clouds surrounding the moon may be secured on the plate.

**W. D.**—Metallic silver in powder, as precipitated from a solution by means of zinc, should be very easily dissolved in equal parts of nitric acid and water; but it is well to use the aid of heat. Set the vessel containing it on the hob. 2. The term "brunette" describes a dark complexion, of the swarthy or olive type, and is generally accompanied by dark hair and eyes; "blonde" describes a fair complexion, skin generally of a pink and white tint, with hair golden, flaxen, or auburn, and eyes generally blue or grey.

**W. G.**—We fear that the advice and information you desire cannot be satisfactorily or decisively given in a few words. The best mode of enlarging is a very moot question, about which much discussion has occurred in our pages, and in photographic societies during the last year or two. There are several modes of enlarging by which good results can be produced; but there is none so simple that a person can readily take up without previous knowledge, and hope to succeed without gaining by experience and learning by failures. There is no work devoted to the subject, but our pages have contained many articles describing various methods. A little pamphlet, published by Mr. Solomon, of Red Lion Square, contains a good deal of information on the subject, especially in relation to enlarging by the aid of magnesium light, a plan which possesses many advantages. We cannot speak with certainty of the salary required by an operator who can undertake such work; probably about two guineas and a-half per week. Get the pamphlet we have recommended, and if you wish for information on any of the methods described, write again.

**H. T. B.**—The Autotype Company and the Woodbury Permanent Printing Company both undertake photo-mechanical printing; but on what terms we cannot tell you. They will doubtless supply the information on application.

**NORMANDY.**—We regret that our information as to precise localities is insufficient to enable us to give satisfactory advice.

**ONE WHOSE AMBITION IS TO EXCEL.**—Your work generally is good; but the portraits are a little low in tone. A slight degree of additional intensity in the negatives would be an advantage. The developers used for your landscapes appear to have answered very well. A little longer exposure, and the same developer would have improved No. 4. Try the albumen process with a collodion substratum, as described in our last YEAR-BOOK. It is possible that bichromated glue may answer for the purpose you mention. Trial alone will certainly decide.

**R. T. J.**—Precipitating the silver in an old bath by means of caustic potash, washing the oxide thoroughly, and re-dissolving in nitric acid is one of the methods proposed many years ago, and, so far as we remember, practised with success. There is no objection to the plan at all that we see, except a little trouble and waste.

**C. B.**—No licence, registration, or formality of any kind is necessary to permit any one to commence practice as a professional photographer.

**H. H. K.**—The source of your trouble is, we think, a very simple one. In transferring the film to the wood you place it the wrong side up. If you place the film on the wood with the image resting on it uppermost, that image will, of course, disappear when you dissolve the film which supports it; but if you reverse the plan, and place the image side next the wood, the image, consisting of a black metallic powder, remains attached to the wood, although the film which covers it is dissolved. Another very simple but more tedious plan of getting an image upon wood without any interfering film consists in making an image in bichromated gelatine, as in the Albertype process, using paper instead of glass; then inking the gelatine image with greasy ink, and transferring to the wood block the impression in greasy ink.

**A MISGUIDED PHOTOGRAPHER** writes to complain of some errors and confusion which have occurred in the recent announcements in relation to the sizes of the pictures intended for the Crawshaw prize competition. Such errors are to be regretted; but, fortunately, they cannot do serious harm, as they are made at a time when all pictures intended for such competition must have been completed before the announcements in question were issued; and it is a pity to dwell upon things which are beyond remedy. The same remark will apply to the comments of "E. T. G.," who suggests that in the circular sent out by the society, the Crawshaw prize list, for want of a distinctive heading, looks like a list of prizes offered by the society.

**LOUIS BUDERUS.**—We regret that your experience with the house in question has been so unsatisfactory, but we of course have no more responsibility or power in the matter in relation to dealers whose announcements appear in our pages, than have the Post Office authorities, who bring these pages to you. We transgressed our usual practice, which is never to take any part in any business transactions of the kind, so far as to call a second time and state your complaint, and were told the goods have been sent off.

**THE LITTLE MAN IN GREEN.**—Your letter reached us just as we were going to press, too late in any case for insertion this week. See above; but we will consider the matter for next week.

**W. H. HARRIS.**—Box safely received. Many thanks. We should have acknowledged it by post, but we have not your address.

**E. H. SPEIGHT.**—Received. Thanks. In our next. Several Correspondents in our next.

## The Photographic News, October 16, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### WOOD ORNAMENTATION BY PHOTOGRAPHY—REVERSING THE IMAGE IN THE CAMERA—ON THE SIDE OF THE PUBLIC—PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

*Wood Ornamentation by Photography.*—An application of photography has recently come under our attention, which is so simple that one can only wonder it has not been more generally adopted. It is the ornamentation of little boxes and cabinets of yellow wood with outline photographs of ferns and flowers, the tops and sides of these receptacles having received an impress by means of light, or been covered with a veneer or coating of some sort, bearing the image. It would be easy, no doubt, to cover the box with bichromate solution of an agreeable tint, dispose of the ferns in an artistic manner, and allow the light to act in the ordinary way; and it would not even matter at all if the top of the cabinets were curved, for the leaves could be pressed in contact just as well. The examples we have seen of this kind of work—outlines of maidenhair and other pretty ferns delicately limned on the exterior of little work-boxes and such like—were very pleasing; and we have no doubt such impressions could be produced with little trouble. At first sight the designs appear to be inlaid like mosaic work, and it is only on a closer inspection that you see there is no division between the straw-coloured wood and the brown or chocolate ground. The expense of producing designs of the same kind by painting or varnishing would doubtless be considerable, compared to the simple depiction of them by means of photography, and we doubt not there are other purposes for which such ornamentation would be just as appropriate and welcome as upon the wooden boxes we refer to.

*Reversing the Image in the Camera.*—According to the *Railway News*, we are informed that Mr. Bryne, a photographer at Margate, has just perfected an ingenious piece of apparatus, which, when placed in front of the camera, throws the image upon the screen in its proper position. The name chosen for this instrument is the "Rectoptrion," which means "to show upright," and by its aid photographers will be saved the trouble of having to view things upside down. Moreover, we are informed that the image is to be seen with the instrument three times its usual brilliancy and colour; and the *Railway News* trusts that every photographer will possess himself of this useful and delightful addition to the camera. We are quite unaware of the nature of this instrument, but we should doubt very much whether the same would be either useful or delightful. Most photographers would tell you that it is perfectly immaterial to them whether they see the picture upside down or not; and, indeed, so accustomed are they to the matter, that they never remark that there is anything peculiar about the image. As to adding to the brilliancy and intensity of light and colour, this could only be the case in the event of the image being, at the same time, much reduced in size, for otherwise, by adding a correcting glass, there would be a loss, rather than a gain, in brilliancy. It may not, by the way, be generally known that our own eyes see everything upside down; thus, if you dissect the eye of any animal, and take the same into a room illuminated simply by a candle, you will perceive, on looking at the retina of the eye, that the flame of the candle is there reflected upside down, and not in its proper position. Whether our brain corrects this or not is a moot point; but certain it is that, so far as the retina or focussing screen of our eye is concerned, the world is therein depicted topsy-turvy.

*On the Side of the Public.*—A little while ago a paper appeared in one of the popular magazines entitled "On the Side of the Maids," which took up the cudgels on behalf of domestic servants against their mistresses. In the same way, we think, something might be written on behalf of

the public against the photographer. We hear from time to time a good deal about how the public ought to be treated, oppressed, and put down; how they should be made to conform blindly to regulations, and deport and carry themselves, and not breathe a syllable of their hopes and wishes until they are outside the studio again. "We know what you are going to say; now pray be quiet, and do not talk nonsense," should be the gist of the photographer's suave remarks to his sitter, according to some authorities. We do not mean to say our friends are wrong; on the contrary, in most cases they are perfectly right, for a photographer's practice and experience are generally very great, and he knows quite well what a lame result will probably be the issue if he allow his sitter, and not himself, to order matters. But for all that, there is something to be said on the side of the public, and the humble suggestions they sometimes make are not always so worthless as they are held to be. The other day we heard two ladies—sisters, and nearly of a height—complaining of a group they recently had taken: a London picture had not given satisfaction, and they believed if the model who had been sitting had been permitted to stand, a more pleasing effect would have been secured, as the figure of the former was rather slimmer and better proportioned than the other. So they had another picture taken at a sea-side studio this time, politely requesting that the desired grouping might be adopted. The photographer was amiable to the last, but inflexible, the lady who was a shade the taller being again requested to sit, and the other to stand; he knew no other law than this, and had to be obeyed. No matter what the forms of the models might be, his notions of art seemed confined to this point, that the taller model must invariably sit. The ladies complained they would be only too glad if they could get a picture to their liking, but such a thing seemed really impossible, and after their two-fold experience they had of course given up the matter as impracticable.
